Big data science Day 3

F. Legger - INFN Torino

https://github.com/leggerf/MLCourse-INFN-2021

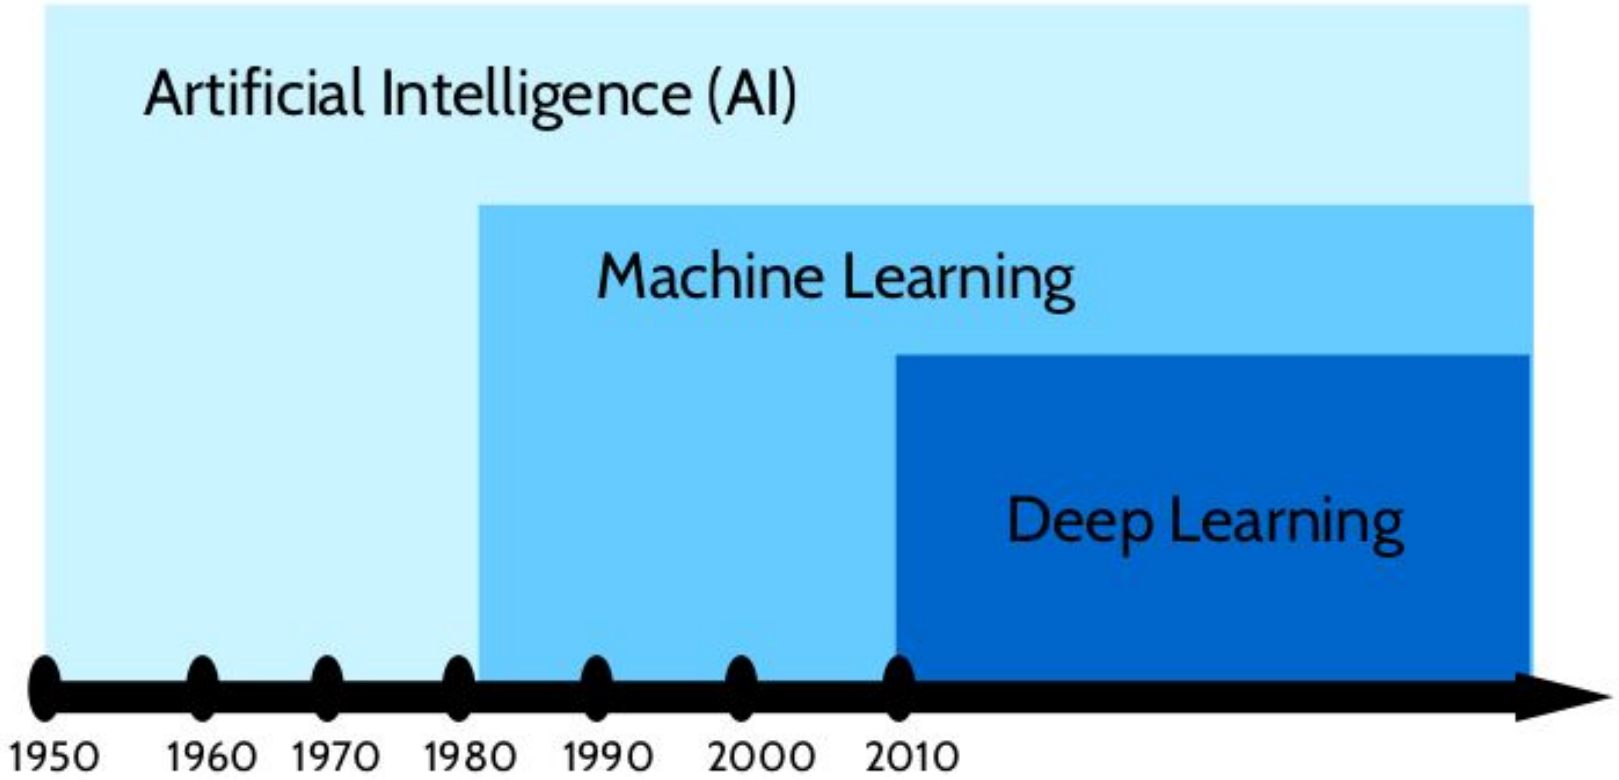
Yesterday

- Big data
- Analytics
- Machine learning

Today

- **Deep learning**
- Parallelisation
- Heterogeneous architectures
- Future directions

Deep Learning is a subfield of ML concerned with algorithms inspired by the structure and function of the brain called artificial neural networks [Jason Brownlee]



Machine translation

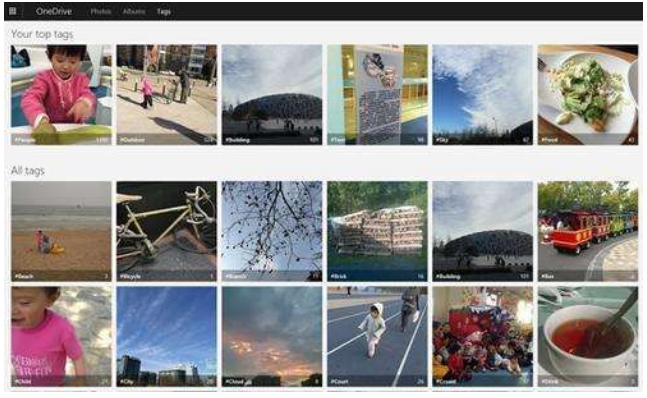
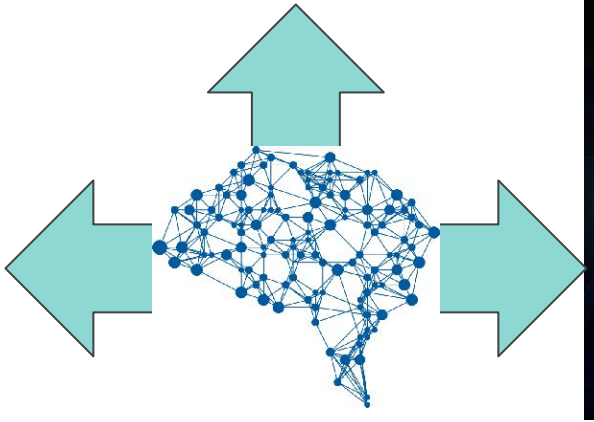
Strategy games
DeepMind beats Go world champion (2017)

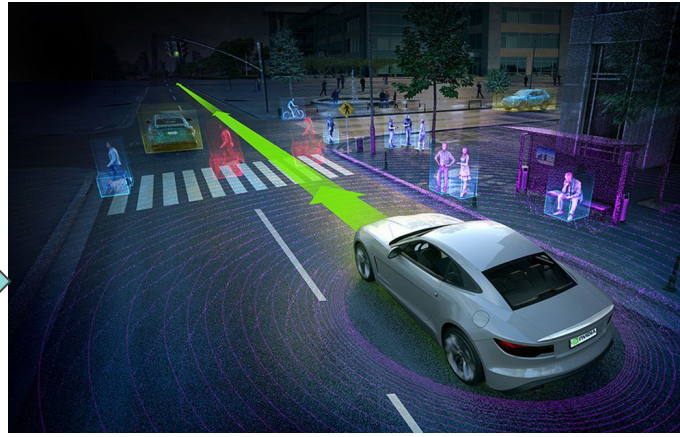
Creativity

Visual recognition



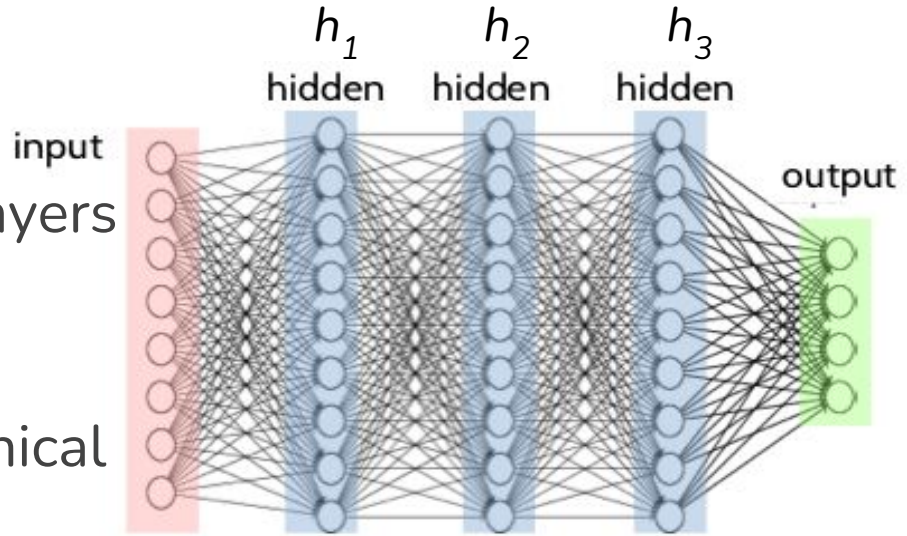


Self driving cars



Deep Learning

- Neural network with several layers
  - Deep vs shallow
- A family of parametric models which learn non-linear hierarchical representations:



$$a_L(\mathbf{x}; \mathbf{\Theta}) = h_L(h_{L-1}(...(h_1(\mathbf{x}, \boldsymbol{\theta}_1), \boldsymbol{\theta}_{L-1}), \boldsymbol{\theta}_L)$$

input

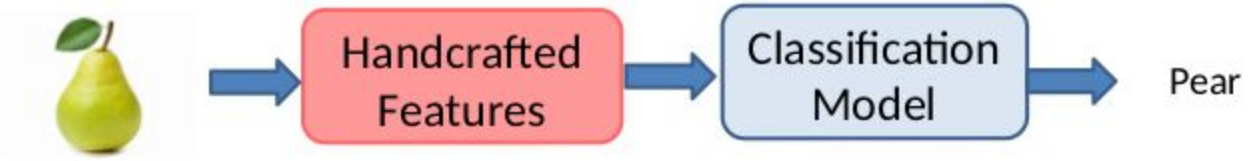
parameters of the network

non-linear activation function

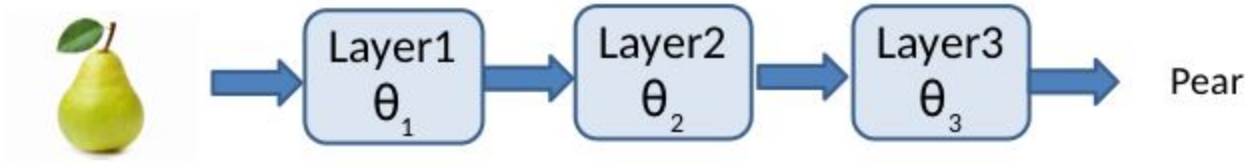
parameters of layer *L*

Learning hierarchical representations

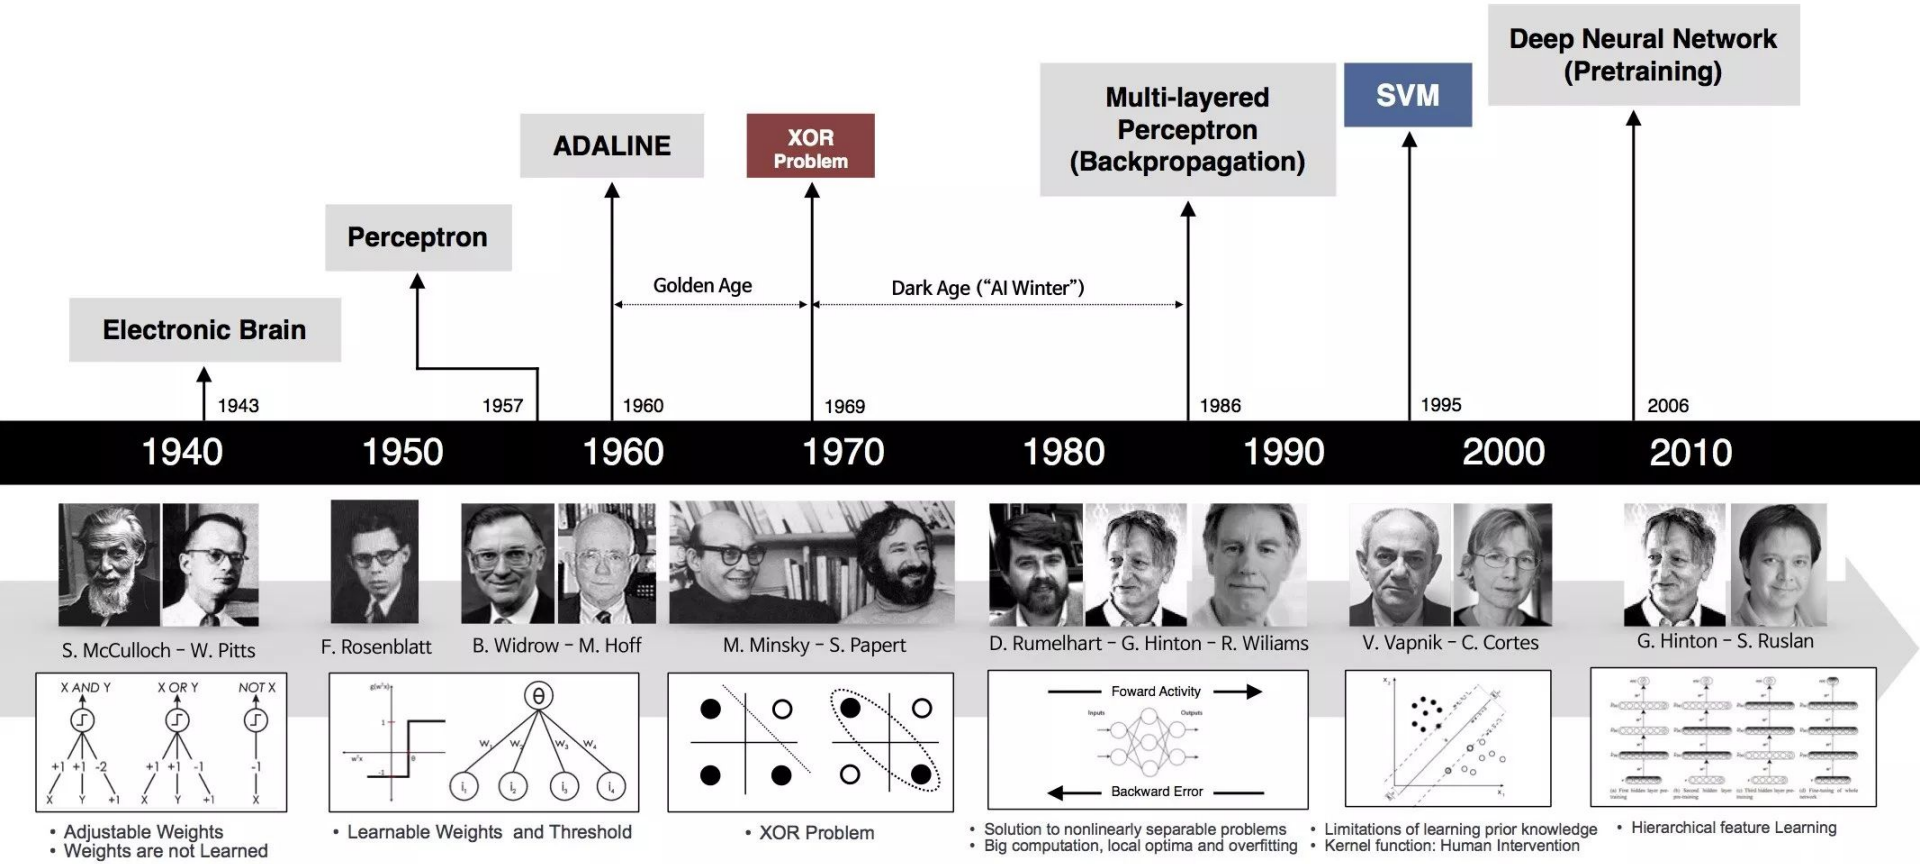
- Traditional framework



- Deep Learning

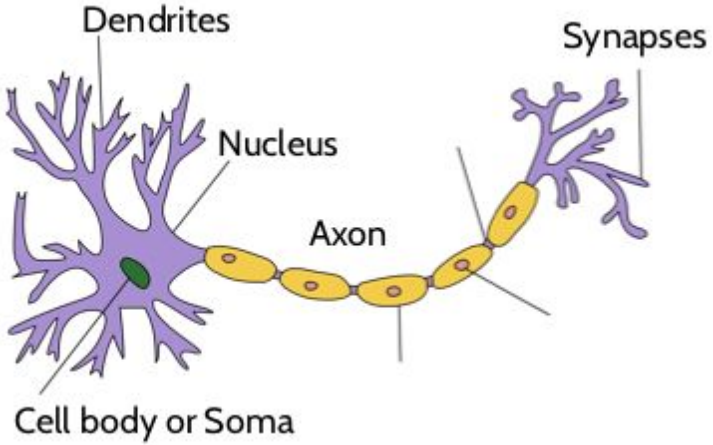


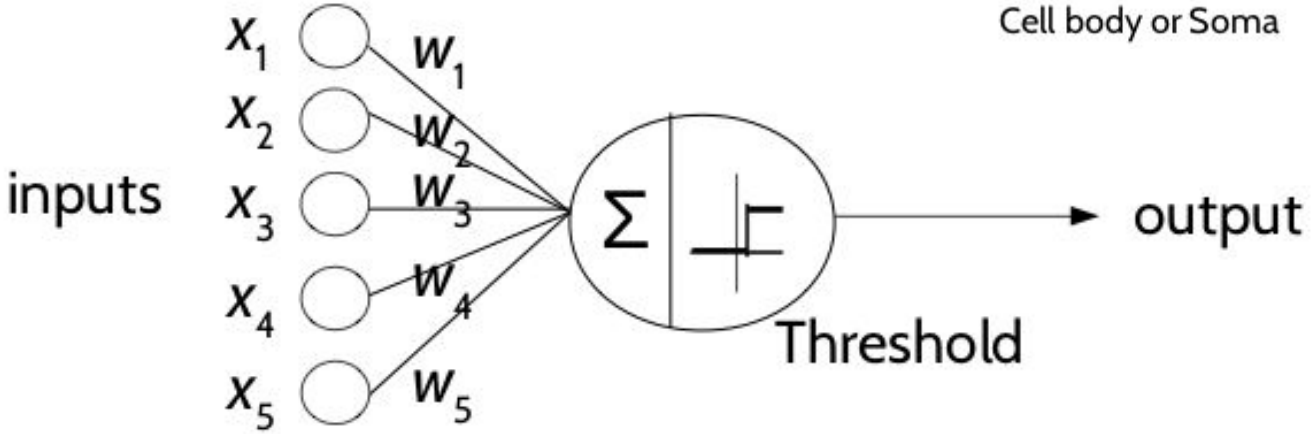
Brief history of neural networks



1943 – McCulloch & Pitts Model

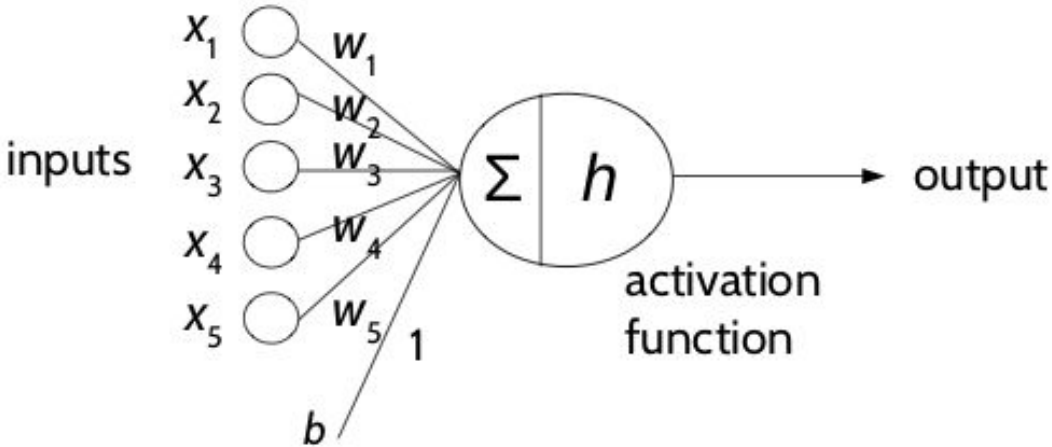
- Early model of artificial neuron
- Generates a binary output
- The weights values are fixed

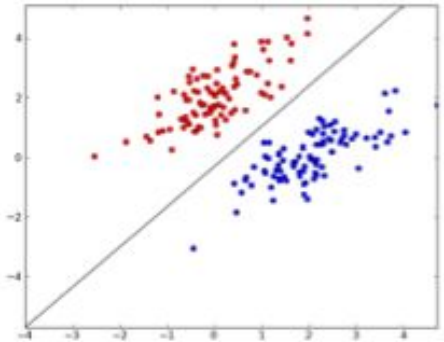




1958 – Perceptron by Rosemblatt

- Perceptron as a machine for linear classification
- Main idea: Learn the weights and consider bias.
  - One weight per input
  - Multiply weights with respective inputs and add bias
  - If result larger than **threshold** return 1, otherwise 0

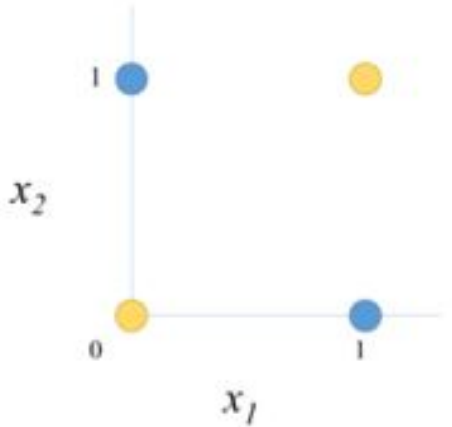


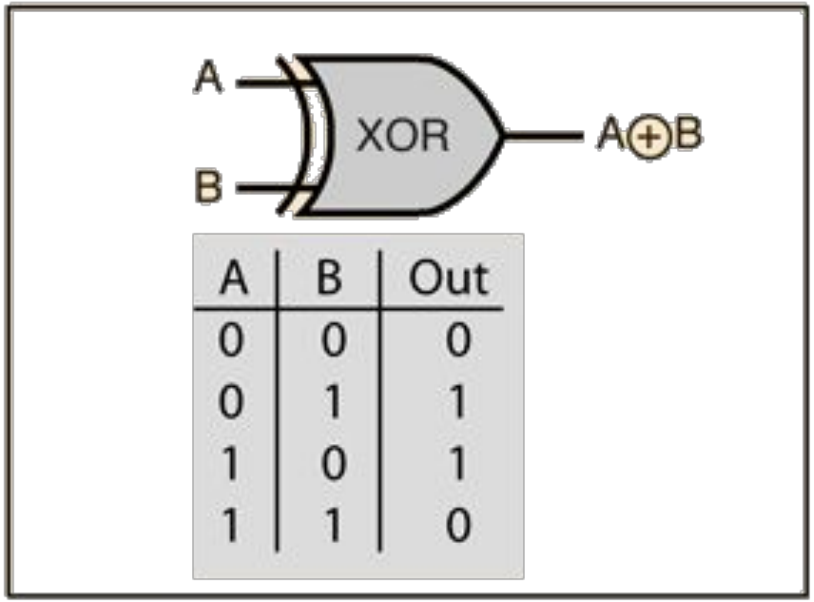


First NN winter

- 1970- Minsky. The XOR cannot be solved by perceptrons.

- Neural models cannot be applied to complex tasks.



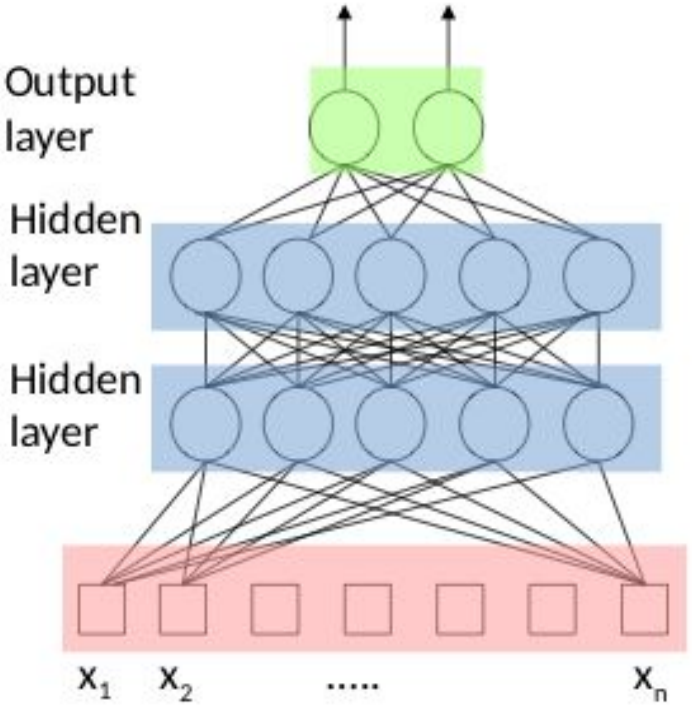


A	B	Out
0	0	0
0	1	1
1	0	1
1	1	0

Multi-layer Feed Forward Neural Network

- 1980s. Multi-layer Perceptrons (MLP) can solve XOR.

- ML Feed Forward Neural Networks:
  - Densely connect artificial neurons to realize compositions of non-linear functions
  - The information is propagated from the inputs to the outputs
  - The input data are usually *n*-dimensional feature vectors
  - Tasks: Classification, Regression



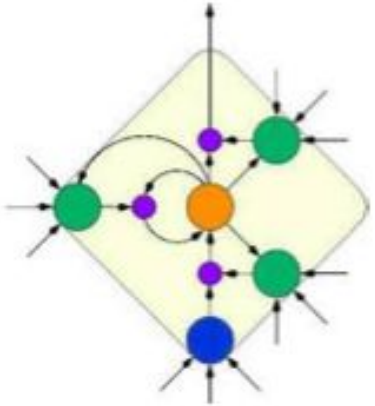
How to train it?

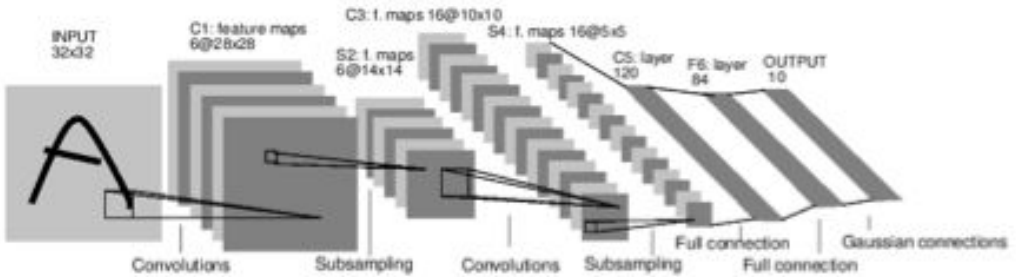
- Rosenblatt algorithm* not applicable, as it expects to know the desired target
  - For hidden layers we cannot know the desired target
- Learning MLP for complicated functions can be solved with **Back propagation (1980)**
  - efficient algorithm for complex NN which processes large training sets

* Remember? Rosenblatt developed a method to train a single neuron

1990s - CNN and LSTM

- Important advances in the field:
  - Backpropagation
  - Recurrent Long-Short Term Memory Networks (Schmidhuber, 1997)
  - Convolutional Neural Networks - LeNet: OCR solved before 2000s (LeCun, 1998).

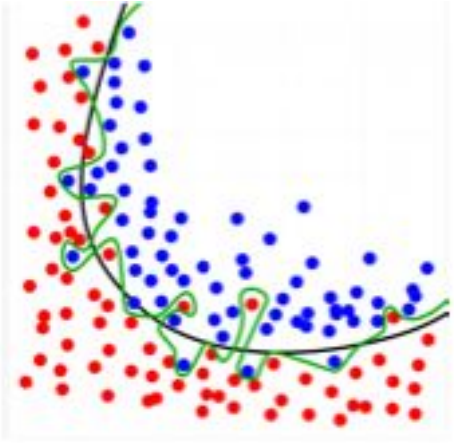


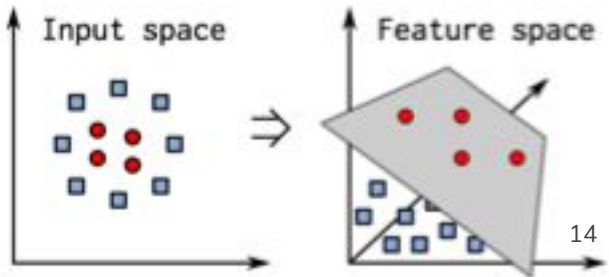


OCR: Optical character recognition

Second NN Winter

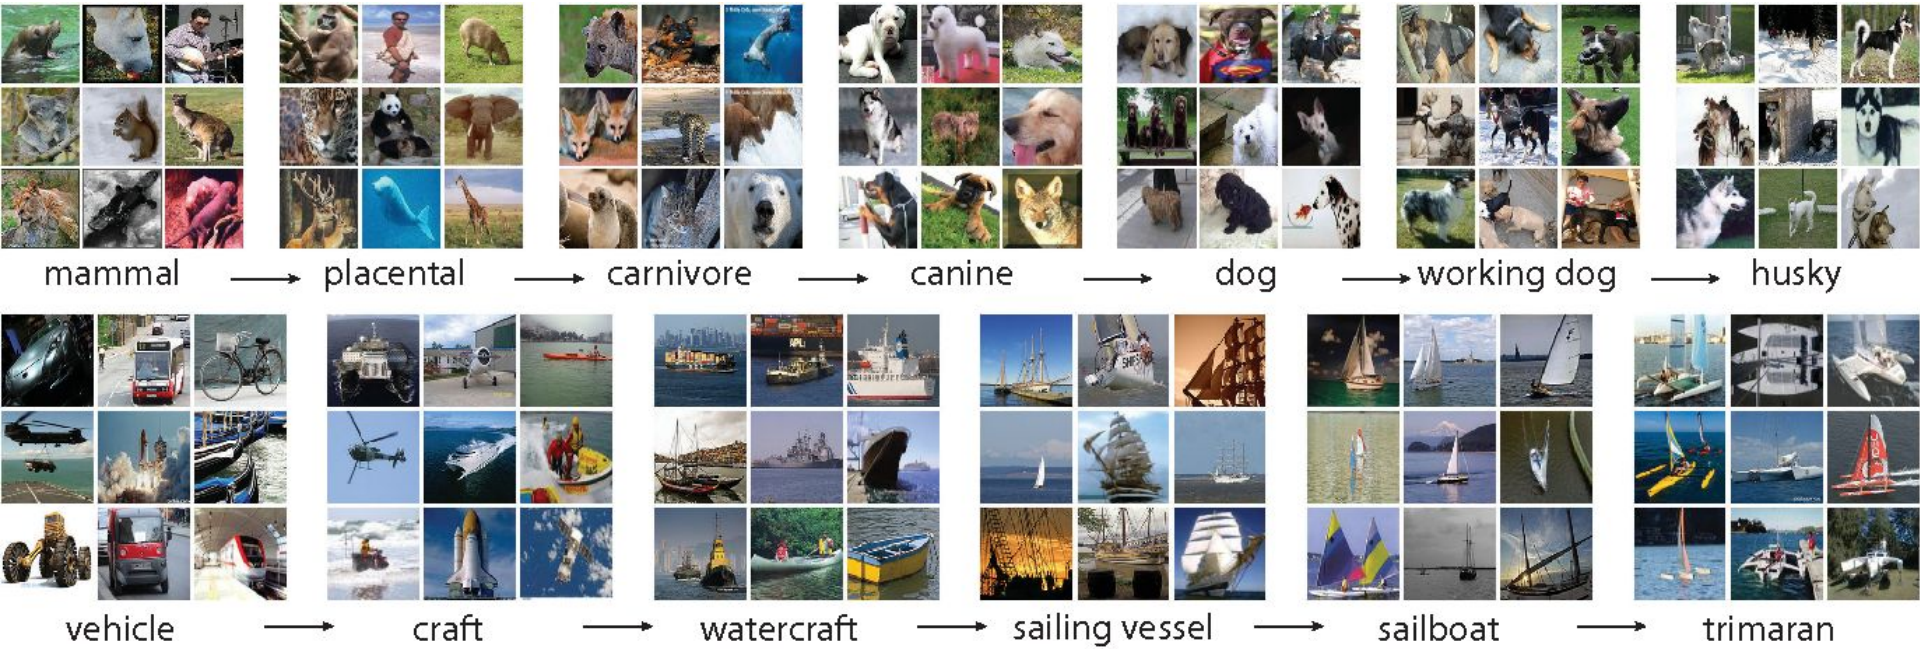
- NN cannot exploit many layers
  - Overfitting
  - Vanishing gradient (with NN training you need to multiply several small numbers → they become smaller and smaller)
- Lack of processing power (no GPUs)
- Lack of data (no large annotated datasets)
- Kernel Machines (e.g. SVMs) suddenly become very popular





ImageNet

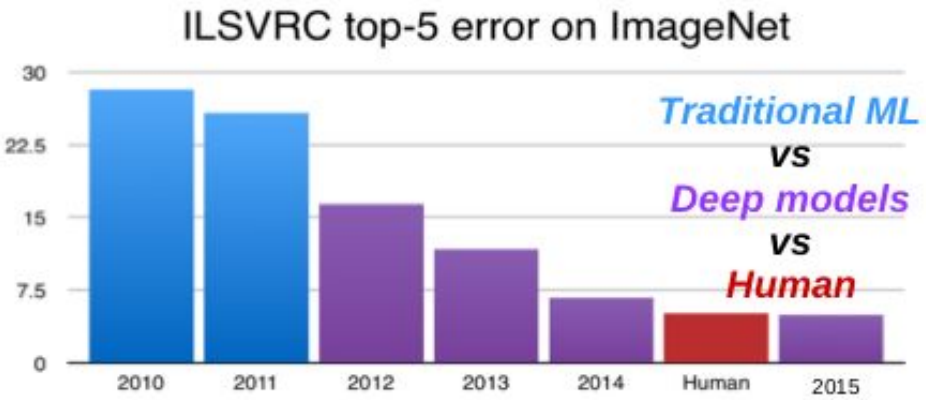
A Large-Scale Hierarchical Image Database (2009)



https://ieeexplore.ieee.org/stamp/stamp.jsp?tp=&arnumber=5206848&tag=1

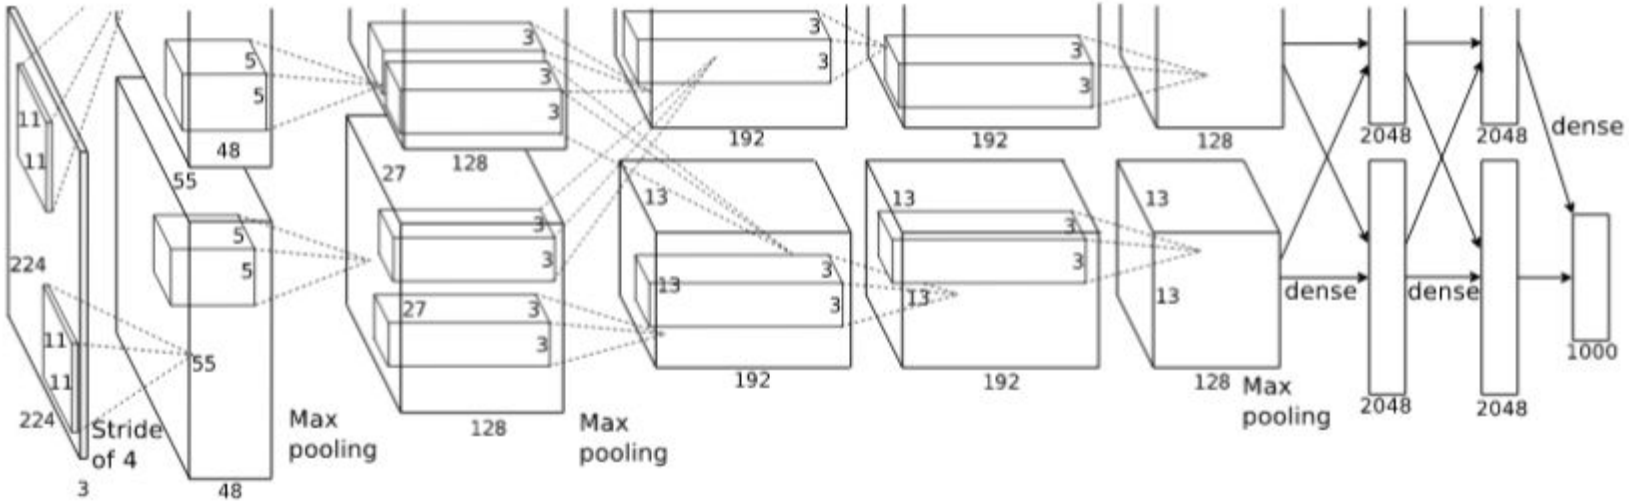
2012 - AlexNet

- Hinton's group implemented a CNN similar to LeNet [LeCun1998] but...
  - Trained on ImageNet (1.4M images, 1K categories)
  - With 2 GPUs
  - Other technical improvements (ReLU, dropout, data augmentation)



https://papers.nips.cc/paper/4824-imagenet-classification-with-deep-convolutional-neural-networks.pdf

AlexNet

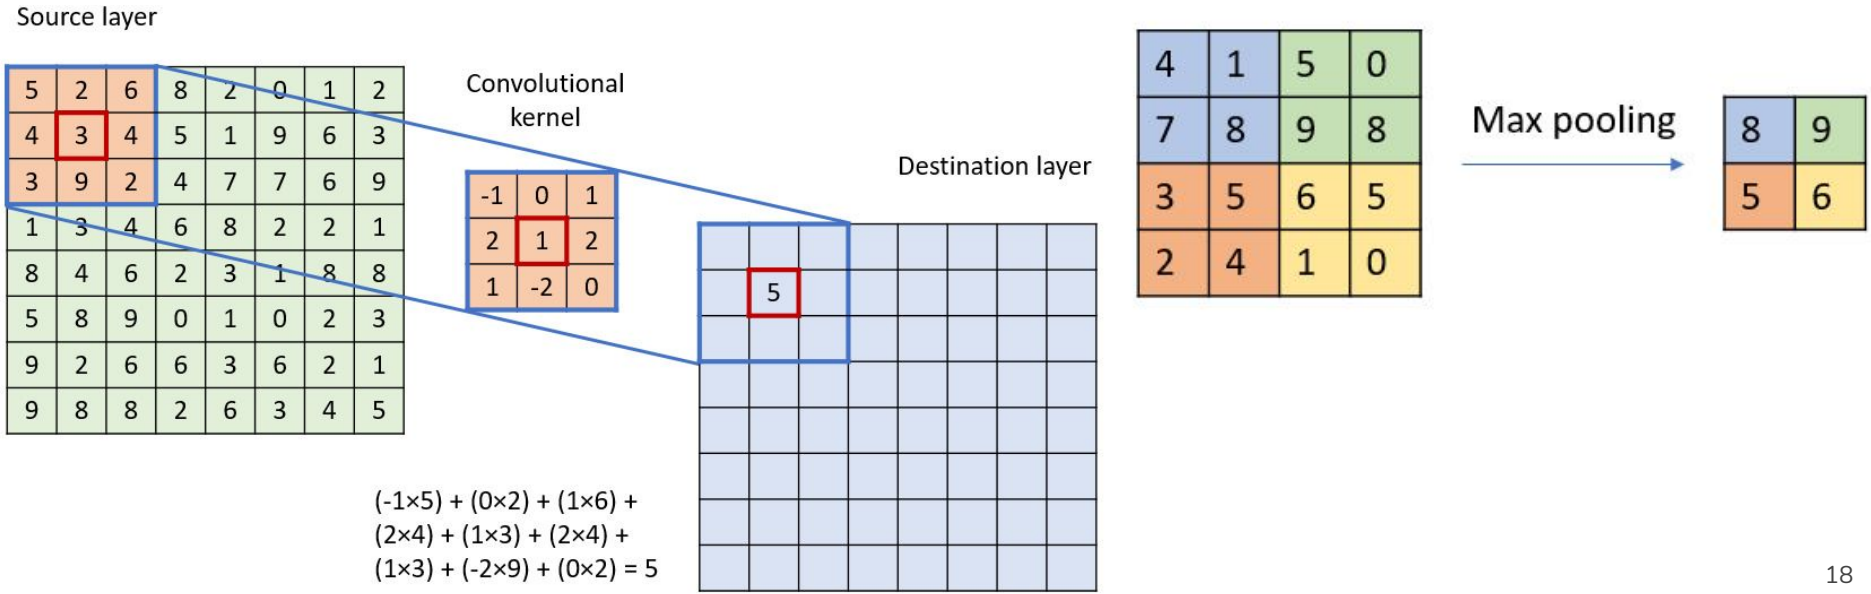


- 60M parameters
- Limited information exchange between GPUs

https://papers.nips.cc/paper/4824-imagenet-classification-with-deep-convolutional-neural-networks.pdf

Convolutional Neural Networks (CNN)

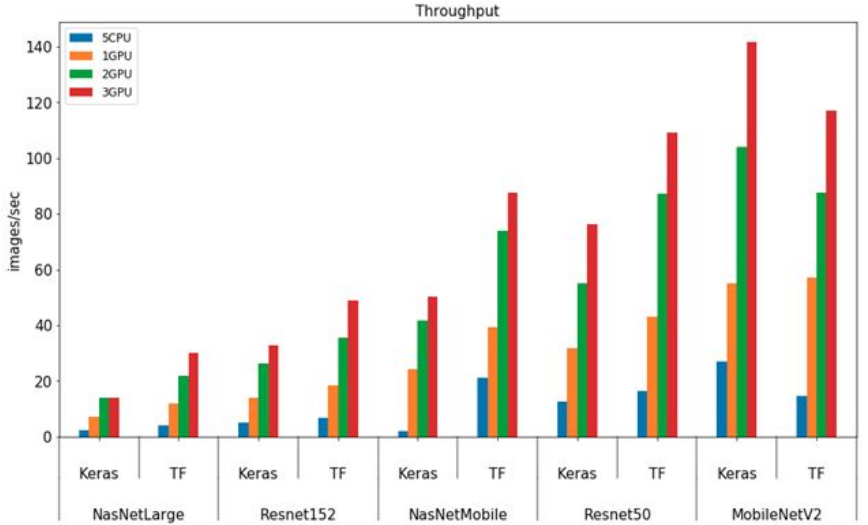
- **Convolutional** layer: two functions produce a third that describes how the shape of one is changed by the other
- **pooling** layer: reduce dimensionality



Why Deep Learning now?

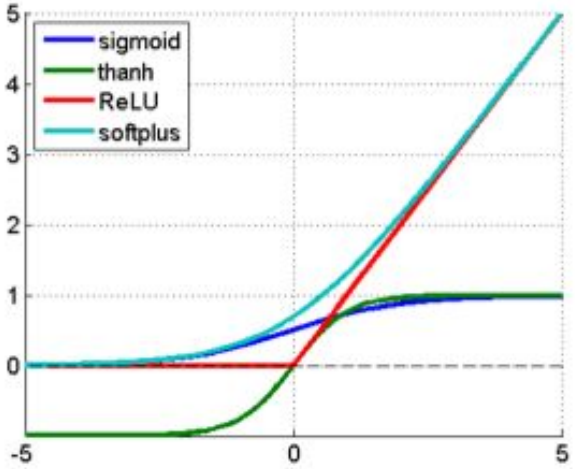
- Three main factors:
  - Better hardware
  - Big data
  - Technical advances:
    - Layer-wise pretraining
    - Optimization (e.g. Adam, batch normalization)
    - Regularization (e.g. dropout)

    ....



Rectified Linear Units (2010)

$$f(x) = \max(0, x)$$

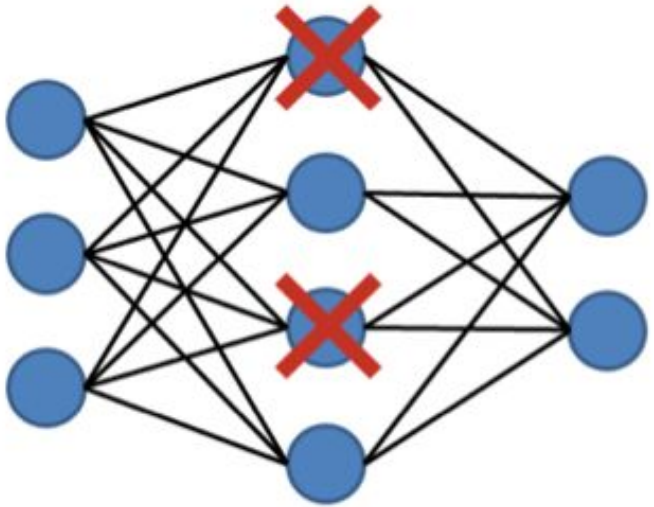


- More efficient gradient propagation: (derivative is 0 or constant)
- More efficient computation: (only comparison, addition and multiplication).
- Sparse activation: e.g. in a randomly initialized networks, only about 50% of hidden units are activated (having a non-zero output)

https://www.cs.toronto.edu/~fritz/absps/reluICML.pdf

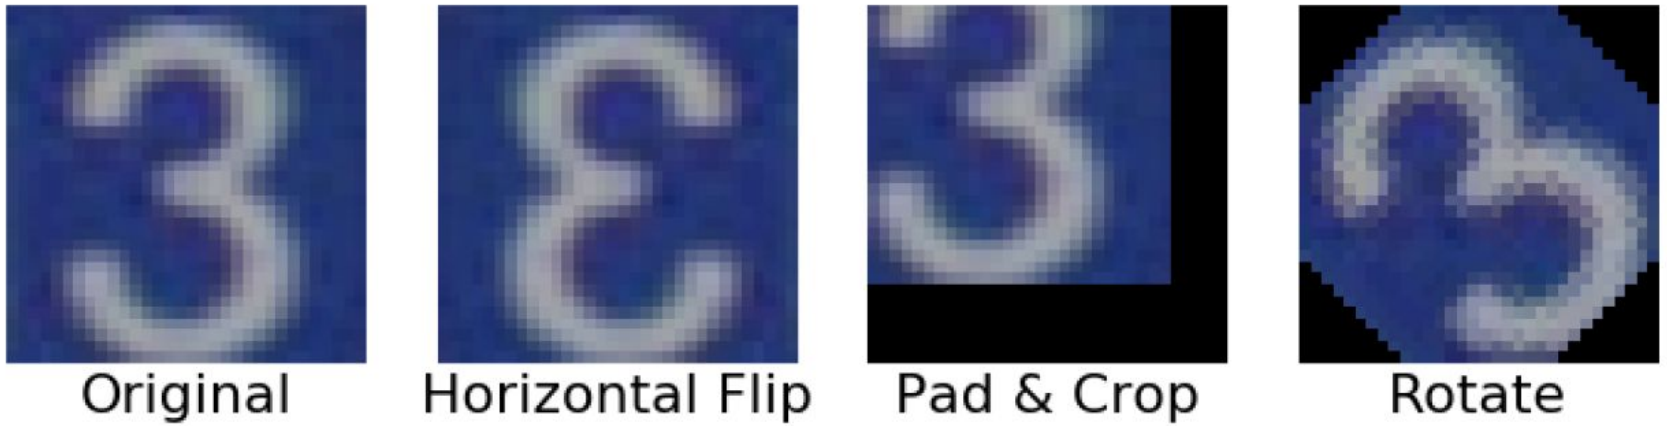
Regularization - Dropout

- For each instance drop a node (hidden or input) and its connections with probability *p* and train
- Final net just has all averaged weights (actually scaled by 1-*p*)
- As if ensembling 2^n different network substructures



Data augmentation

- Techniques to significantly increase the diversity of data available for training models, without actually collecting new data
- Data augmentation techniques such as cropping, padding, and horizontal flipping are commonly used to train large neural networks



Training a neural network

Name	Weight (lb)	Height (in)	Gender
Alice	133	65	F
Bob	160	72	M
Charlie	152	70	M
Diana	120	60	F

- Predict gender from weight and height

Feature engineering

- Symmetrize numeric values
- Category -> numbers

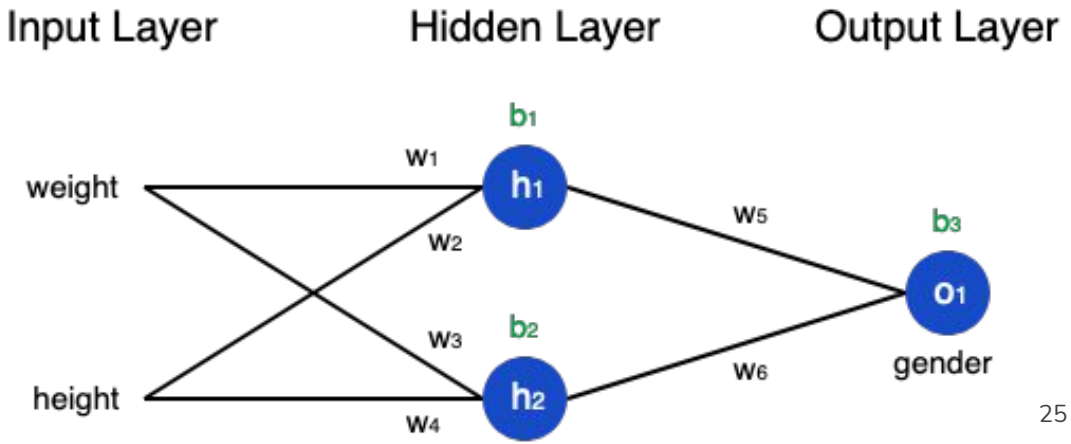
Name	Weight (lb)	Height (in)	Gender
Alice	133	65	F
Bob	160	72	M
Charlie	152	70	M
Diana	120	60	F

Name	Weight (minus 135)	Height (minus 66)	Gender
Alice	-2	-1	1
Bob	25	6	0
Charlie	17	4	0
Diana	-15	-6	1

Ingredients

- **n** : 4, number of samples (Alice, Bob, Charlie, Diana)
- **y** : variable being predicted (Gender)
- $\mathbf{y}_{\mathbf{true}}$: true value of y, $\mathbf{y}_{\mathbf{pred}}$: predicted value of y = **o**
- Loss function **L: MSE**
- Activation function **f**
- Outputs of the hidden layer **h**
- Unknown parameters: weights **w** and biases **b**

$$\text{MSE} = \frac{1}{n}\sum_{i=1}^{n}(y_{true} - y_{pred})^2$$



Back propagation

- **Training the network == minimize the loss**
  - Find weights **w** and biases **b**
  - $L(w_1, w_2, w_3, w_4, w_5, w_6, b_1, b_2, b_3)$
- Minimization taking partial derivatives (**back propagation**)

$$\boxed{\frac{\partial L}{\partial w_1} = \frac{\partial L}{\partial y_{pred}} * \frac{\partial y_{pred}}{\partial h_1} * \frac{\partial h_1}{\partial w_1}}$$

For very simple case: with only Alice in the dataset, n=1

$$L = (1 - y_{pred})^2$$

$$\frac{\partial L}{\partial y_{pred}} = \frac{\partial (1 - y_{pred})^2}{\partial y_{pred}}$$

$$y_{pred} = o_1 = f(w_5 h_1 + w_6 h_2 + b_3)$$

$$\frac{\partial y_{pred}}{\partial h_1} = \boxed{w_5 * f'(w_5 h_1 + w_6 h_2 + b_3)}$$

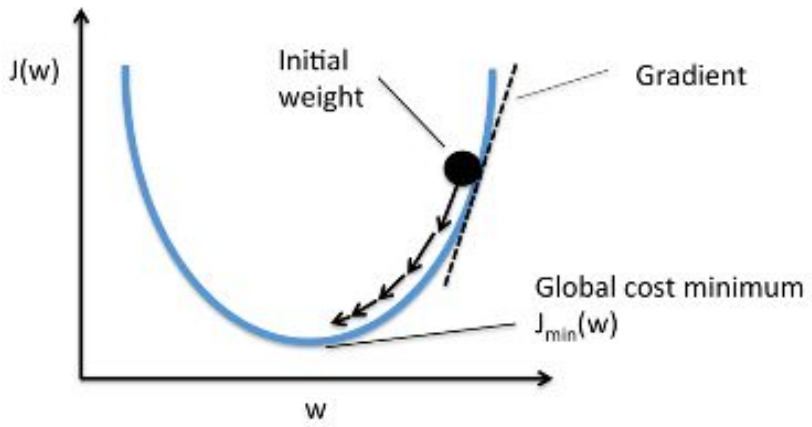
$$h_1 = f(w_1 x_1 + w_2 x_2 + b_1)$$

$$\frac{\partial h_1}{\partial w_1} = \boxed{x_1 * f'(w_1 x_1 + w_2 x_2 + b_1)}$$

Stochastic Gradient Descent (SGD)

- optimization algorithm to find weights and biases to minimize loss
- **update equation**:

$$w_1 \leftarrow w_1 - \eta \frac{\partial L}{\partial w_1}$$



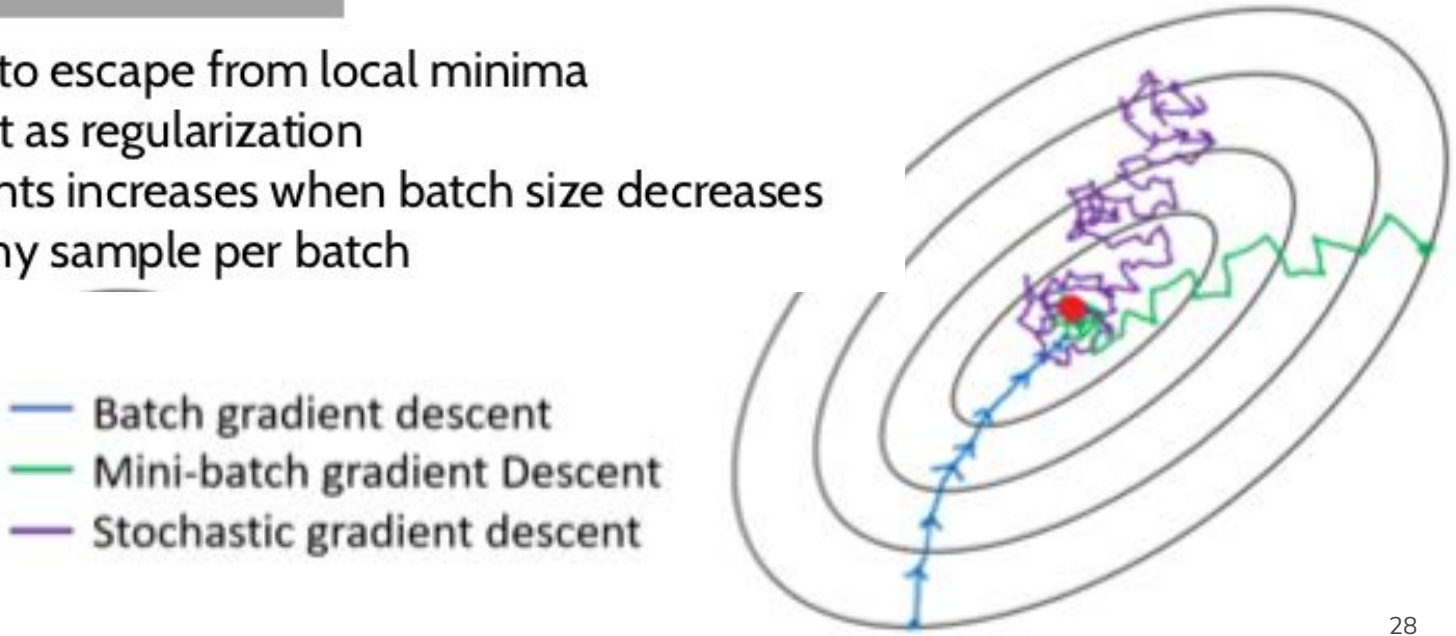
- **η** is a constant called the **learning**
- If $\frac{\partial L}{\partial w_1}$ is positive, w_1 will decrease, which makes L decrease.
- If $\frac{\partial L}{\partial w_1}$ is negative, w_1 will increase, which makes L decrease.
- **Stochastic** -> the parameters are updated using only a single training instance (usually randomly selected) in each iteration

Stochastic gradient descent (SDG)

- Use mini-batch **sampled** in the dataset for gradient estimate.

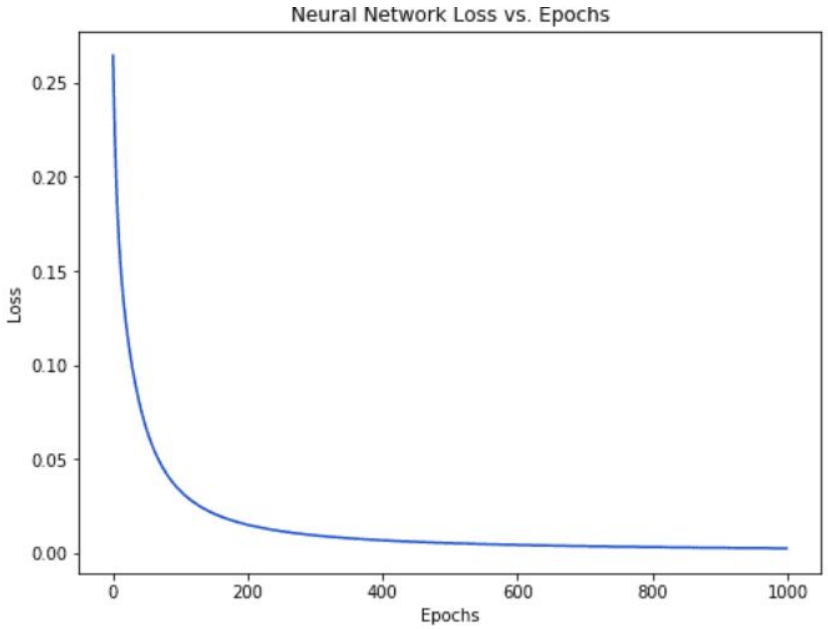
$$\Theta^{t+1} = \Theta^t - \frac{\eta_t}{|\mathcal{B}|} \sum_{i \in \mathcal{B}} \nabla_\Theta \mathcal{L}_i$$

- Sometimes helps to escape from local minima
- Noisy gradients act as regularization
- Variance of gradients increases when batch size decreases
- Not clear how many sample per batch



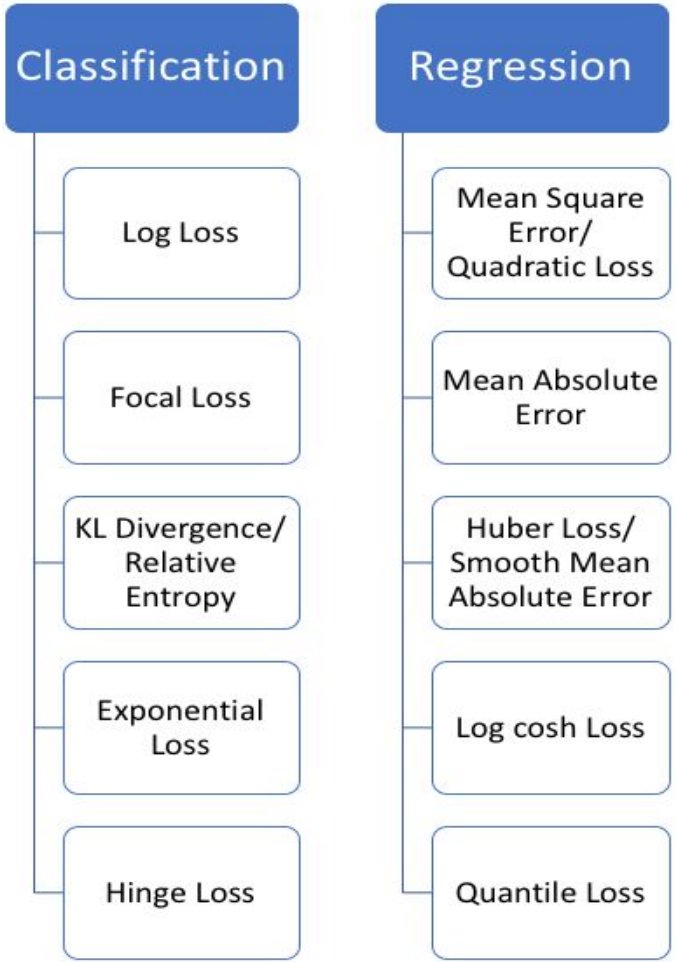
Training the network

- Choose one sample from our dataset
  - This is what makes it stochastic gradient descent - only operate on one sample at a time
- Calculate all the partial derivatives of loss with respect to weights or biases
- Use the update equation to update each weight and bias
- Iterate



Loss functions

- https://heartbeat.fritz.ai/5-regression-loss-functions-all-machine-learners-should-know-4fb140e9d4b0
- https://www.wikiwand.com/en/Loss_functions_for_classification



Regularization

- One of the major aspects of training the model is overfitting -> the ML model captures the noise in your training dataset
- The **regularization** term is an addition to the loss function which helps generalize the model
  - **L1** or Lasso regularization adds a penalty which is the sum of the absolute values of the weights
    - L1+MSE

$$Min(\sum_{i=1}^{n}(y_i - w_i x_i)^2 + p\sum_{i=1}^{n}|w_i|)$$

  - **L2** or Ridge regularization adds a penalty which is the sum of the squared values of weights
    - L2+MSE

$$Min(\sum_{i=1}^{n}(y_i - w_i x_i)^2 + p\sum_{i=1}^{n}(w_i)^2)$$

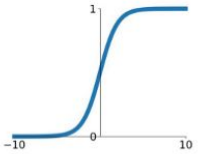
- **Dropout** in NN context: hidden nodes are dropped randomly
- **Early Stopping** is a time regularization technique which stops training based on given criteria

Activation functions

- Classification: sigmoid functions
  - sigmoids and tanh functions are sometimes avoided due to the vanishing gradient problem
- **ReLU** function is a general activation function
- dead neurons in our networks -> the leaky ReLU
- ReLU function should only be used in the hidden layers
- As a rule of thumb, start with ReLU

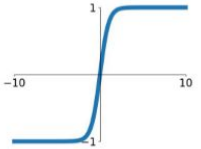
Sigmoid

$$\sigma(x) = \frac{1}{1+e^{-x}}$$



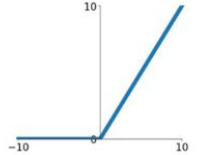
tanh

$$\tanh(x)$$



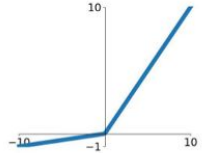
ReLU

$$\max(0, x)$$



Leaky ReLU

$$\max(0.1x, x)$$



Maxout

$$\max(w_1^T x + b_1, w_2^T x + b_2)$$

ELU

$$\begin{cases} x & x \geq 0 \\ \alpha(e^x - 1) & x < 0 \end{cases}$$

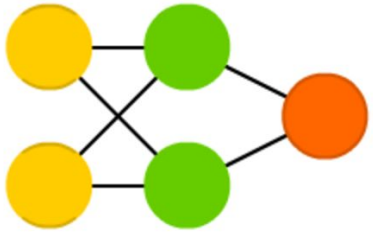
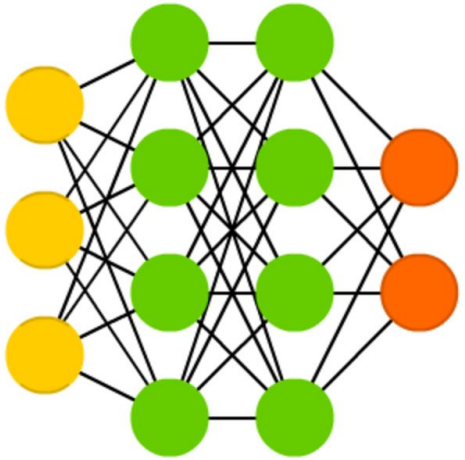
Feed Forward

- Supervised, simplest form of NN
- The data passes through input nodes and exits on the output nodes
- Easy to implement and combine with other type of ML algorithms
- Typically trained with backpropagation
- Used in many ML tasks, speech, image recognition, classification, computer vision
- input/outputs are vectors of fixed length
- **DFF** is a FF NN with more than one hidden layer

Feed Forward (FF)

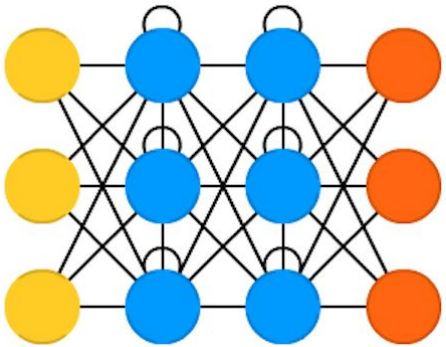


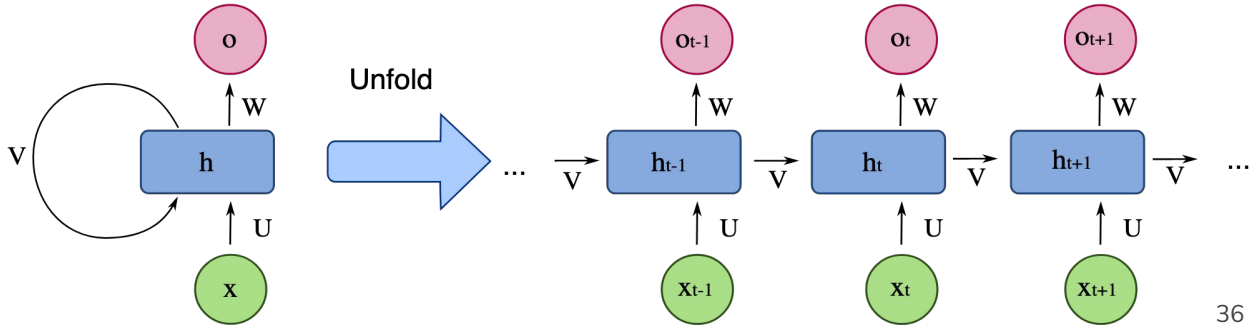
Deep Feed Forward (DFF)



Recurrent Neural Network (RNN)

- FFNN with **Recurrent Cells**: hidden cell that receives its own output with fixed delay
- RNNs permit to operate on **sequences of vectors** (in the input, the output, or both)
- RNNs, once unfolded in time, can be seen as very deep FF networks in which all the layers share the same weights





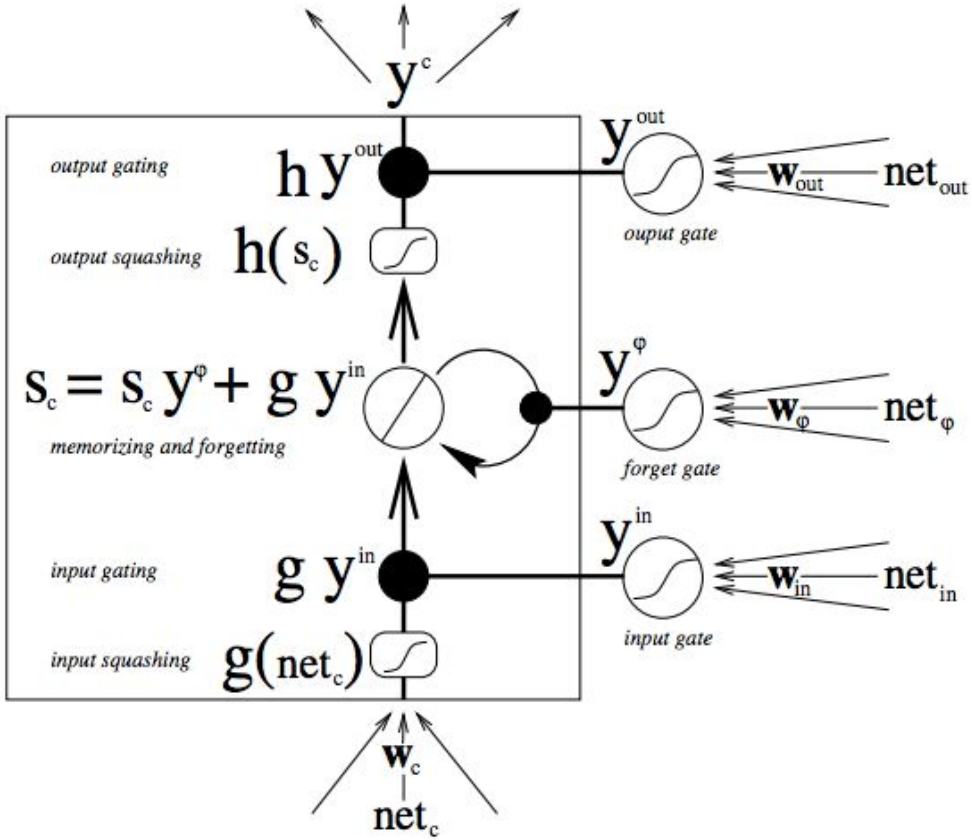
Recurrent Neural Network (RNN)

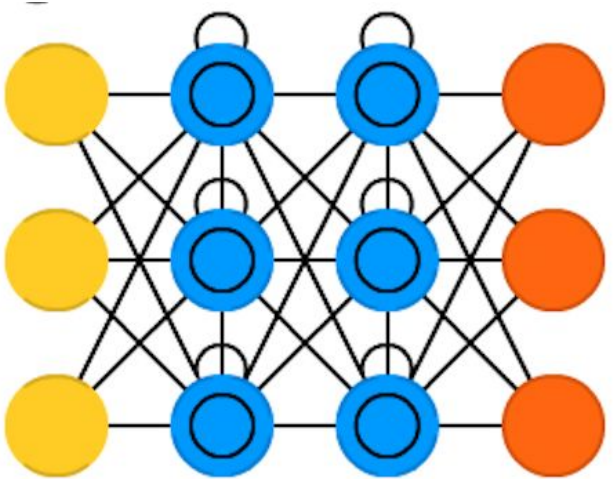
- The parameters to be learned are shared by all time steps in the network
- The gradient at each output depends also on the calculations of the previous time steps
- context is important, decision from past iterations can influence current state
- a word can be analyzed only in context of previous words or sentences

Long/Short Term Memory (LSTM)

- RNNs not really capable of learning long term dependencies
  - Due to vanishing gradient with increasing time steps
  - -> add cells with memory: “keep in mind” previous info, e.g. something that happened many frames ago
- A common LSTM unit is made of a **cell**, an i**nput**, an **output** and a **forget** gate
- The cell remembers values over arbitrary time intervals and the three gates regulate the flow of information into and out of the cell

Long/Short Term Memory (LSTM)

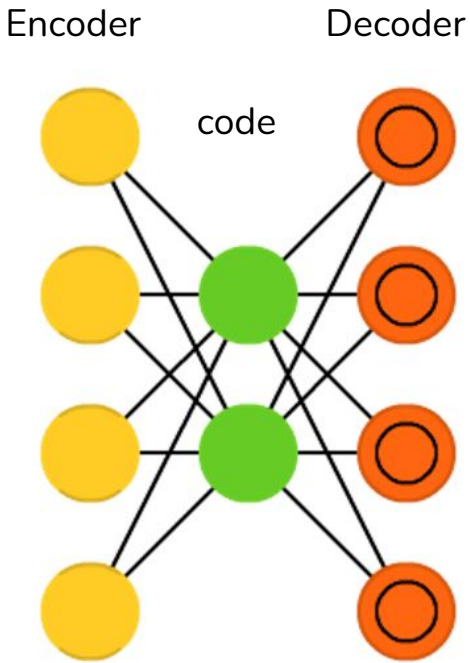




Auto Encoders

- **Unsupervised** learning
  - find smaller representation of given input and search for common patterns
- Compress (encode) information automatically.
- An **encoder** is a deterministic mapping *f* that transforms an input vector *x* into hidden representation *y*
- A **decoder** maps back the hidden representation *y* to the reconstructed input *z* via *g*.
- **Autoencoder**: compare the reconstructed input *z* to the original input *x* and try to minimize the reconstruction error
- used for classification, clustering and feature compression

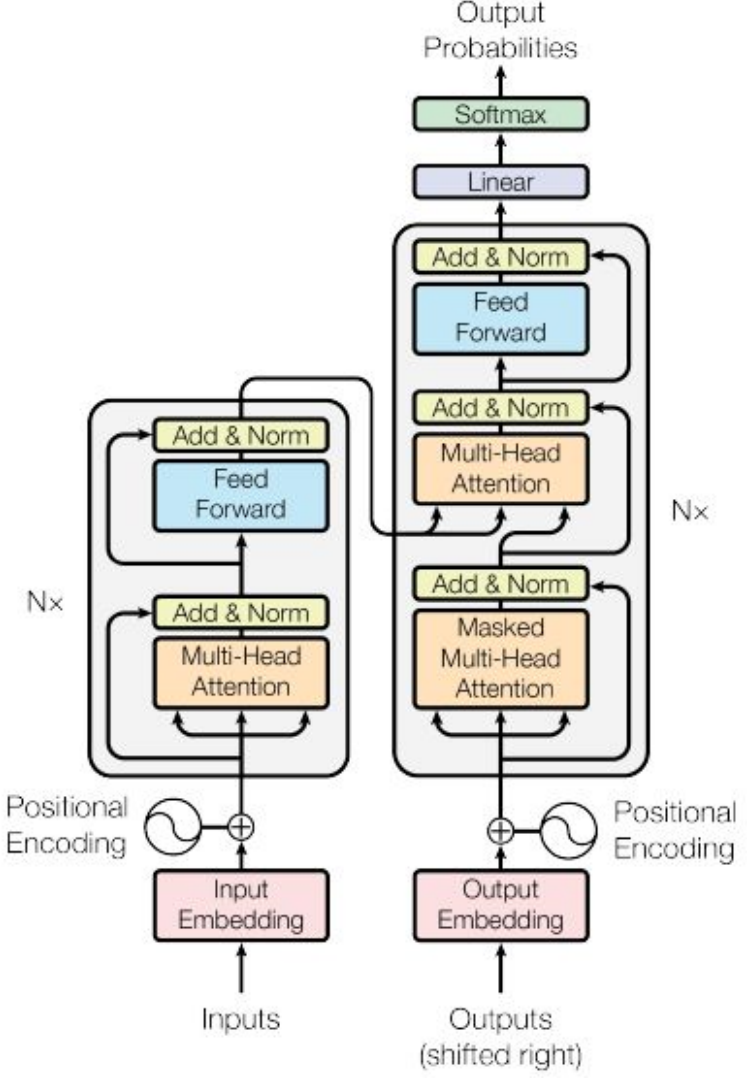
Auto Encoders



Transformers (2017)

- All you need is attention
- Self-**attention: query, key, value**:
  - the output is a weighted sum of the values, where the weight assigned to each value is determined by the dot-product of the query with all the keys:

$$\text{Attention}(Q, K, V) = \text{softmax}(\frac{QK^T}{\sqrt{d_k}})V$$



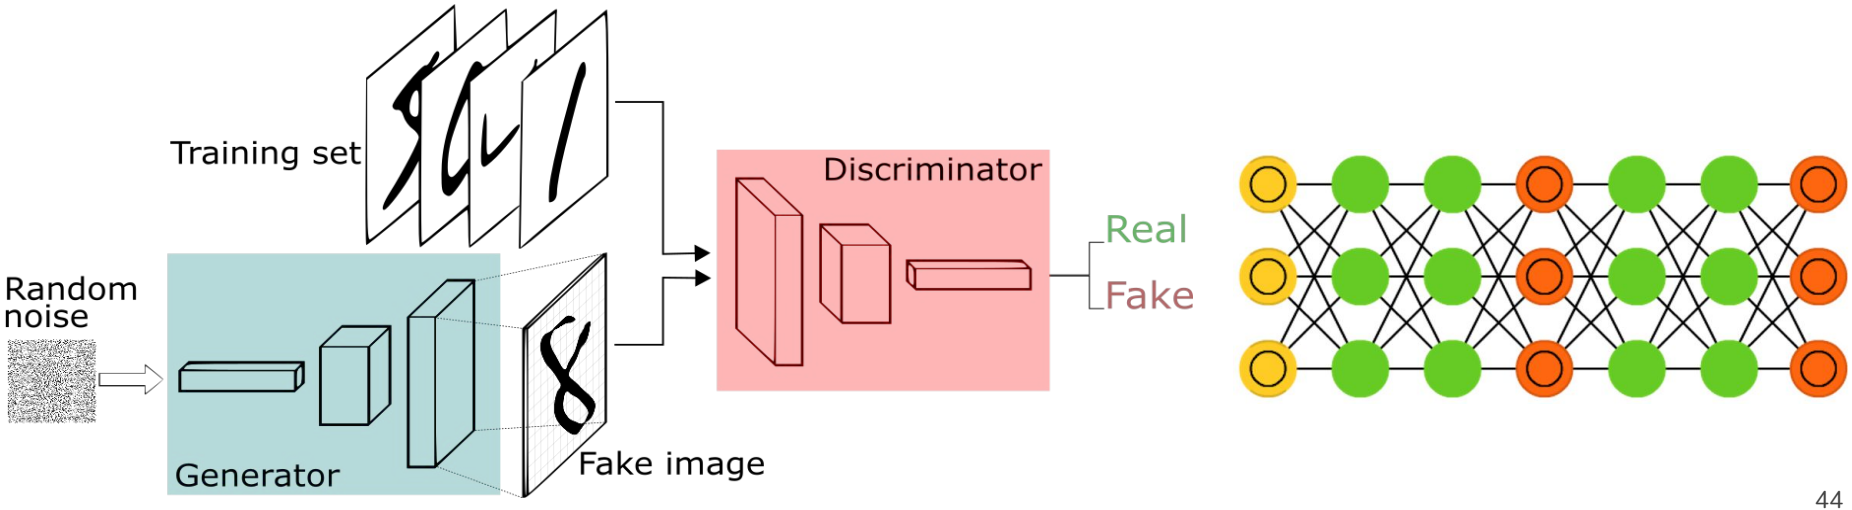
arXiv:1706.03762 [cs.CL]

Generative Adversarial Networks (GAN)

- GANs represent a huge family of double networks that are composed from a **generator** net and a **discriminator** net
  - The generator produces samples close to training samples
  - Discriminator net (adversary) must differentiate between samples from the generative net and the training set
  - Use error feedback to improve task of both nets, until discriminator can no longer distinguish
  - Discriminator net is discarded at test time
- Can be used to generate samples of data without prior knowledge of the data

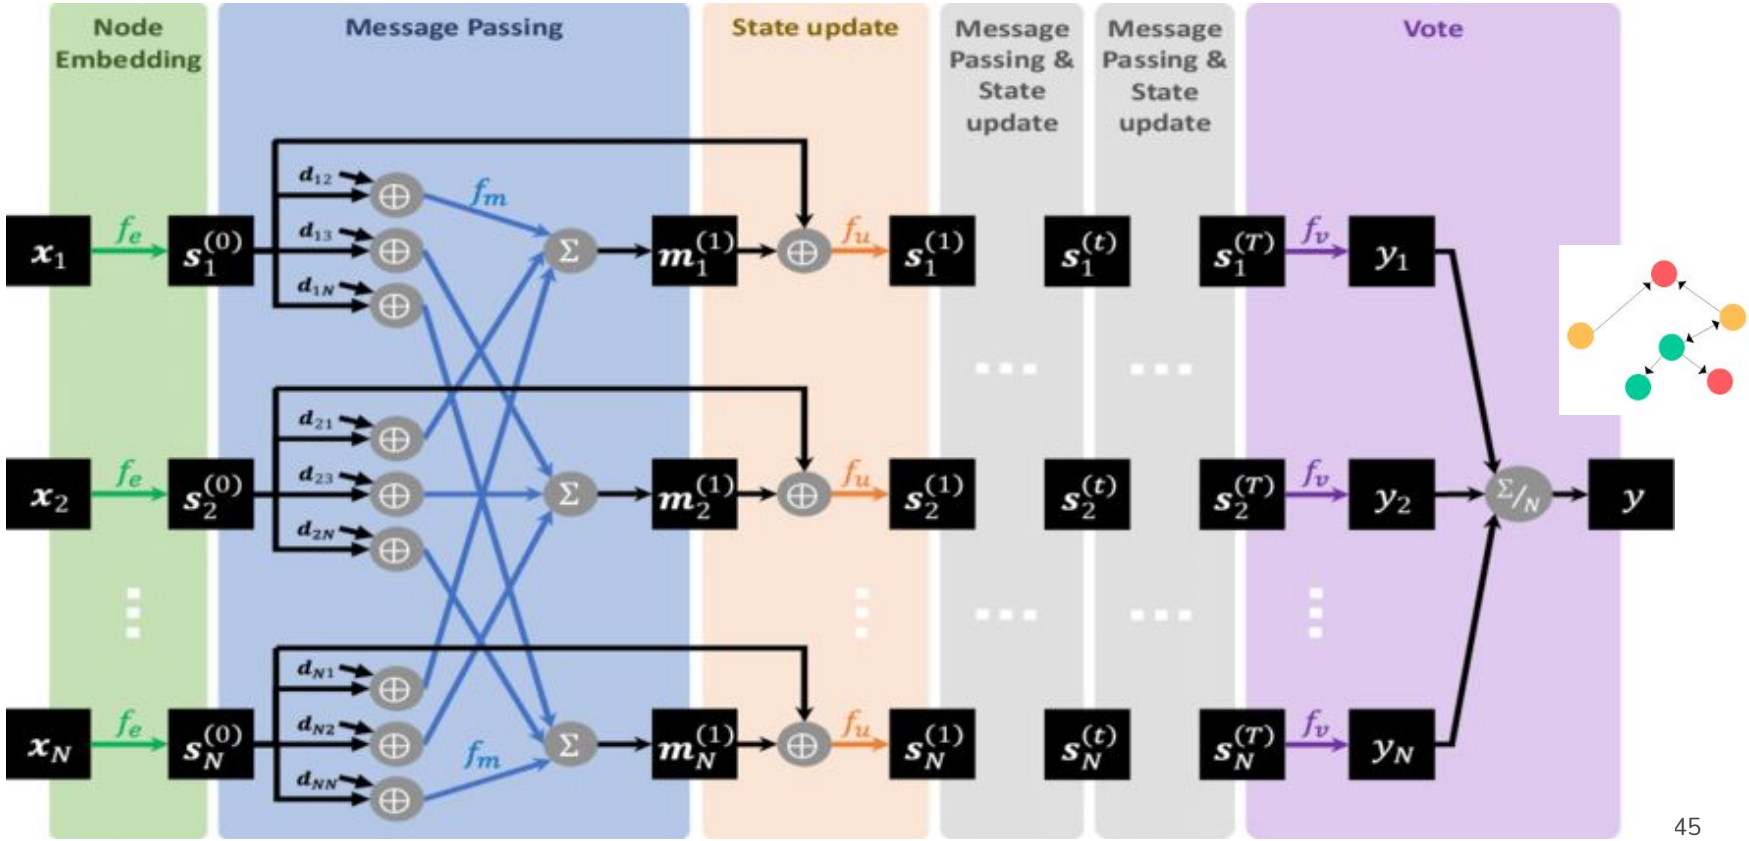
Generative Adversarial Networks (GAN)

- Double network: generator net and discriminator net
  - generator produces samples close to training samples
  - discriminator differentiates samples from generator and training set
  - training until discriminator can no longer distinguish



Graph Neural Network (GNN)

- Node prediction
- Edge prediction
- Graph prediction



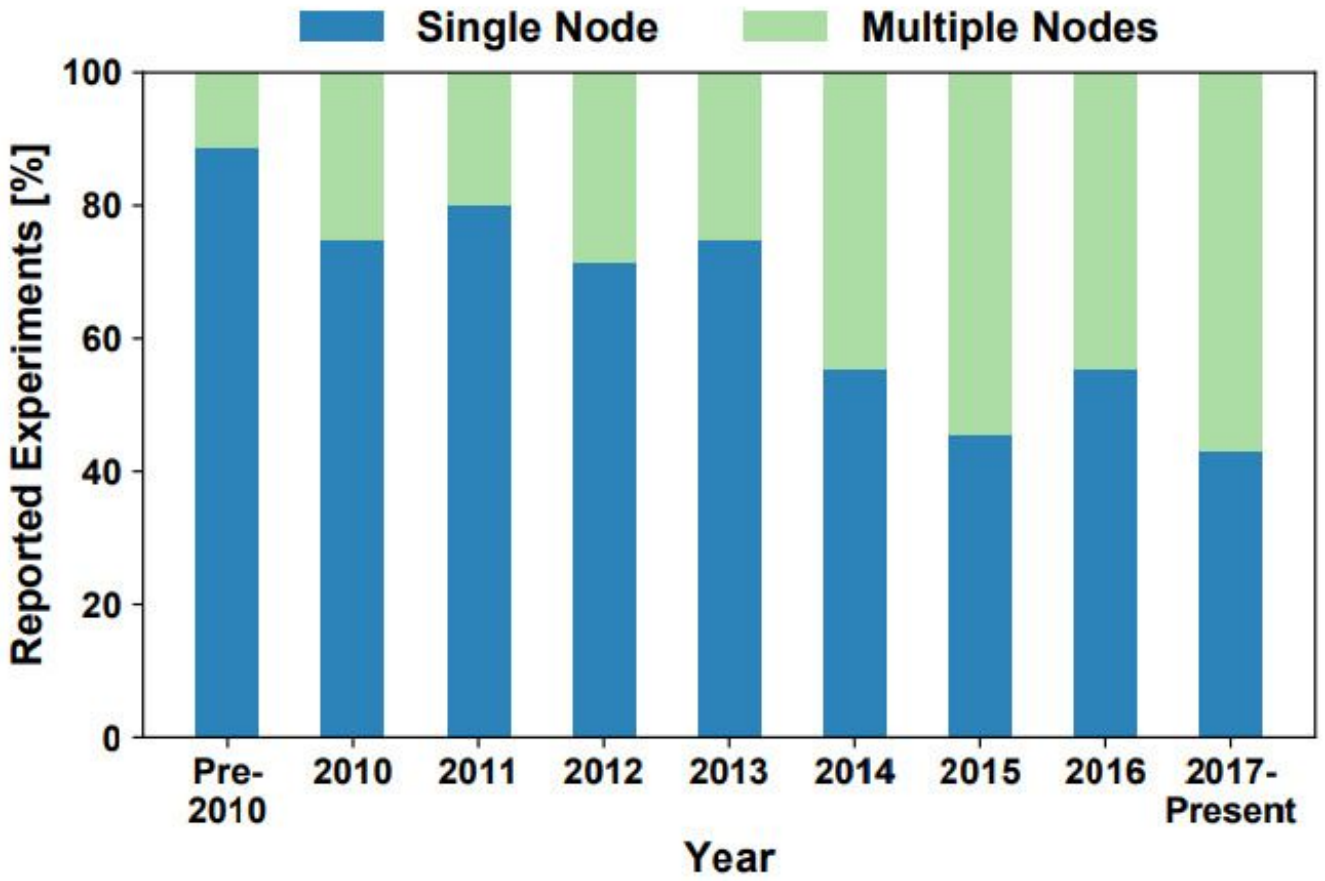
NN evolution in the past 10 years

- 2009: handwriting recognition prizes with LSTM
- 2011 DanNet (CNN) beats humans in **visual pattern recognition**
- 2014: GANs, Alexa, Tesla AutoPilot
- 2015: FaceNet starts facial recognition programs
- 2016: AlphaGo **beats Go champion**
- 2017: Google **Translate** and Facebook Translate based on two LSTMs
- 2018: Cambridge analytica, deep fakes
- 2019: DeepMind defeats professional StartCraft players with RL + LSTM, Rubik's Cube solved with a Robot Hand

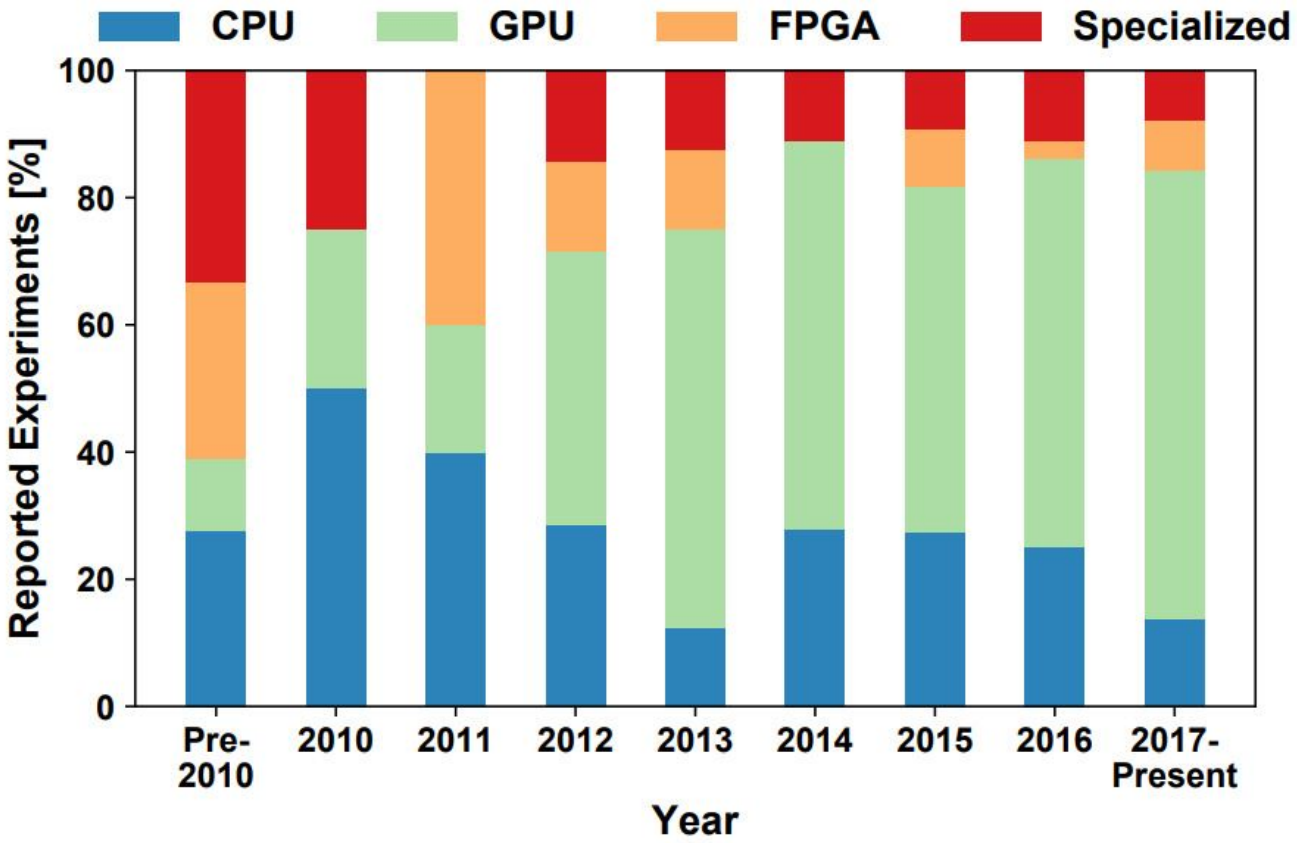
Summary

- Machine learning (ML): family of algorithms with ability to automatically learn and improve from experience without being explicitly programmed
  - potential to approximate linear and non-linear relationships
- For a given problem:
  - find algorithm that will give the best results
  - Train model
  - Tune hyperparameters
  - Do cross-validation
  - Do inference

- Most ML algorithms require significant amount of CPU, RAM and sometimes GPU in order to be applied efficiently
- **Does it fit on your laptop?**



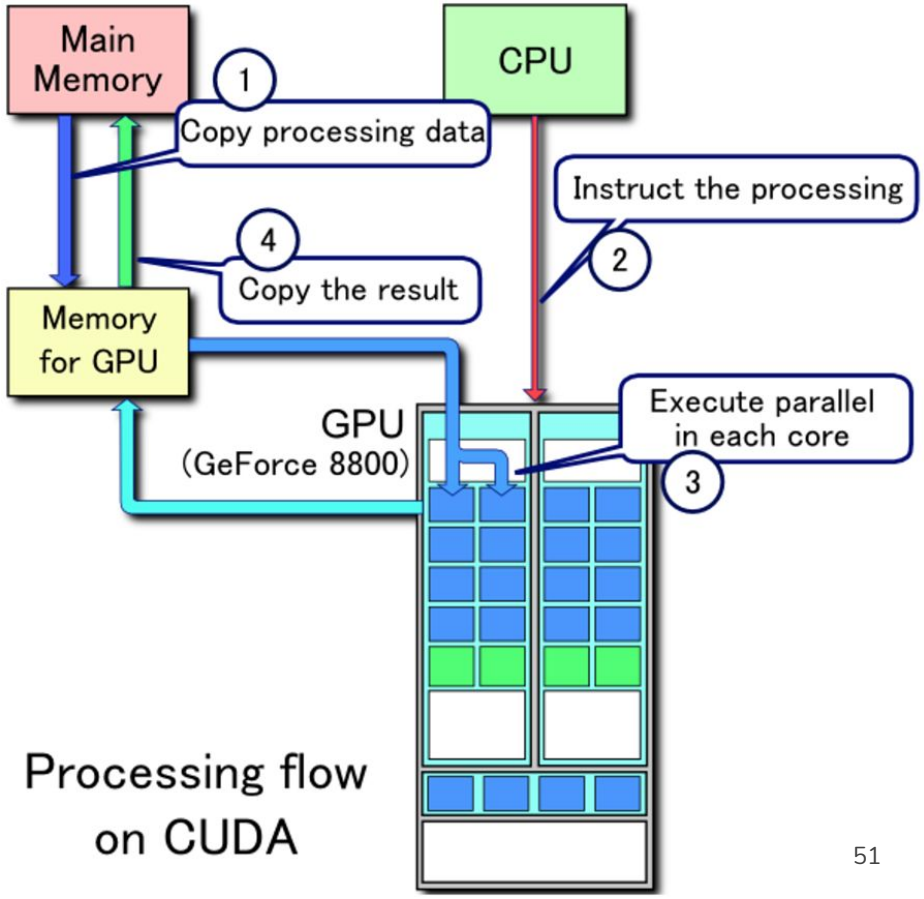
Fraction of non-distributed vs distributed deep learning over time



Use of hardware for deep learning

GPU (Graphical Processing Unit)

- Typically composed of thousands of logical cores
- Excels at matrix and vector operations
  - Gaming, rendering...and ML
- Main vendor: NVidia
  - CUDA: parallel computing platform and programming model



Options

- **NVIDIA CUDA**
  - Market leader, large user community, best support from DL frameworks
  - Can be used in python, C/C++, fortran, Matlab
- **AMD HIP**
  - Limited support for pyTorch and Tensorflow
  - Slightly behind in terms of performances
- **INTEL**
  - Xeon Phi: Poor support
  - Habana Gaudi-based AWS EC2 instances will be available in 2021 (?!?)
- **Google TPU**
  - Good performances, more powerful than cloud GPUs
  - best for training, for prototype and inference better use cheaper alternatives
- **Amazon AWS and Microsoft Azure**
  - Powerful, easy to scale, expensive

How to choose hardware

- **GPUs** have high performance for floating point arithmetic
  - limited amount of memory available
  - rate at which data can be moved from CPU to GPU
  - memory bandwidth for GPUs must be seen relative to the amount of FLOPS: if one has more floating point units, a higher bandwidth is needed to keep them occupied
- **Matrix operations:** typically bandwidth cost is larger than multiplication cost
  - Particularly important for many small multiplications

How to choose hardware

- CNN need a lot of computing power (need high number of cores, FLOPS)
- LSTM and RNN are made of small matrix multiplication: memory bandwidth matters
- Be aware of power consumption and overheating when placing multiple GPUs close to one another!

NVIDIA GPUs

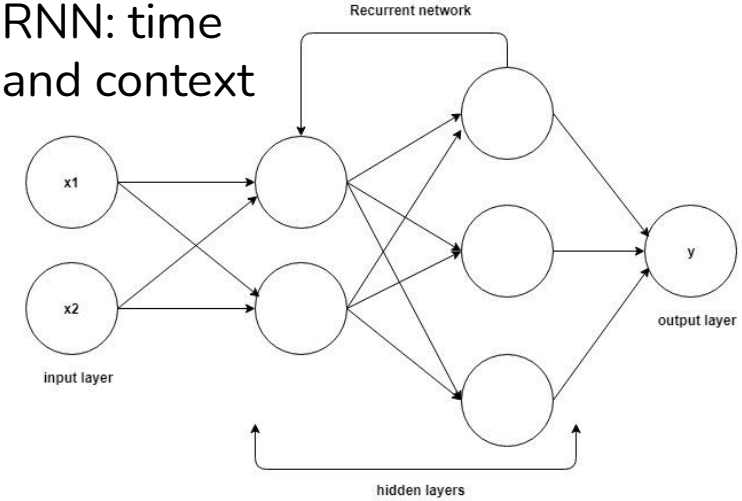
	Peak Performance
Transistor Count	54 billion
Die Size	826 mm^2
FP64 CUDA Cores	3,456
FP32 CUDA Cores	6,912
Tensor Cores	432
Streaming Multiprocessors	108
FP64	9.7 teraFLOPS
FP64 Tensor Core	19.5 teraFLOPS
FP32	19.5 teraFLOPS
TF32 Tensor Core	156 teraFLOPS | 312 teraFLOPS*
BFLOAT16 Tensor Core	312 teraFLOPS | 624 teraFLOPS*
FP16 Tensor Core	312 teraFLOPS | 624 teraFLOPS*
INT8 Tensor Core	624 TOPS | 1,248 TOPS*
INT4 Tensor Core	1,248 TOPS | 2,496 TOPS*
GPU Memory	40 GB
GPU Memory Bandwidth	1.6 TB/s
Interconnect	NVLink 600 GB/s PCIe Gen4 64 GB/s
Multi-Instance GPUs	Various Instance sizes with up to 7MIGs @5GB
Form Factor	4/8 SXM GPUs in HGX A100
Max Power	400W (SXM)

With its multi-instance GPU (MIG) technology, A100 can be partitioned into up to seven GPU instances, each with 10GB of memory.

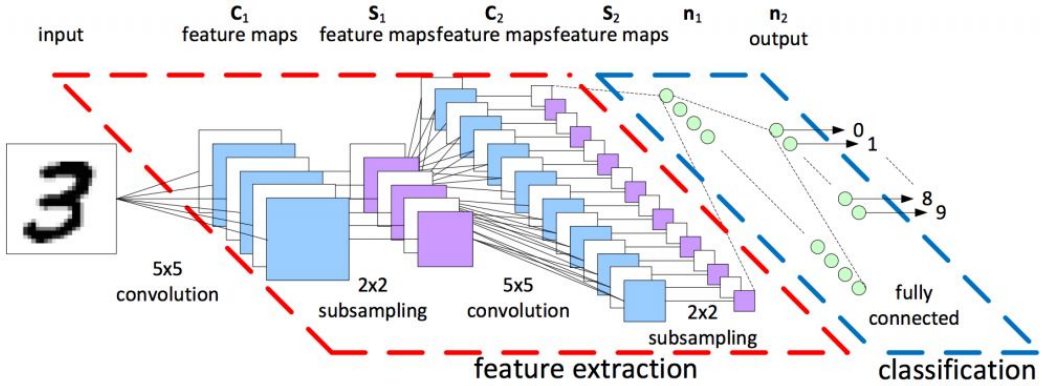
Parallelisation on multiple GPUs

- ‘Easy’ for RNNs and CNNs
- Fully connected networks with transformers poorer performances
- multiple GPUs can be used for tasks trivial to parallelise such as hyperparameter scan

RNN: time and context



CNN: image recognition



Local training

- Both model and data fit on a single machine (**multi cores + GPU**)
  - Multi-core processing:
    - *Embarrassingly parallel process*: use the cores to process multiple images at once, in each layer
    - Use multiple cores to perform SGD of multiple mini-batches in parallel.
  - Use GPU for computationally intensive subroutines like matrix multiplication.
  - Use both multi-core processing and GPU where all cores share the GPU and computationally intensive subroutines are pushed to the GPU.

Distributed training

- Data or model stored across multiple machines
- **Data parallelism**: data is distributed across multiple machines
  - data is too large to be stored on a single machine or to achieve faster training
  - **Synchronous update**: all loss gradients in a given mini-batch are computed using the same weights and full information of the average loss in a given mini-batch is used to update weights
  - **Asynchronous update**: as soon as a machine finishes computing updates, the parameters in the driver get updated. Any machine using the parameters will fetch the updated parameters from the server.

Data parallelism

- large batch of input data split across a collection of workers, each holding the full model
  - the forward pass involves no communication
  - the backward pass involves aggregating the gradients computed by each individual worker with respect to its separate part of the “global batch”
- scaling out:
  - the “global batch size” (i.e. the total number of examples across all workers that are seen in a single forward pass) increases
  - Affects convergence of DL algorithms and does not reach same accuracy levels that can be obtained with smaller batch sizes

Model parallelism

- model layers split across a collection of workers
- the batch size stays constant, and large models that would not fit the memory of a single device can be trained
- active communication also in the forward pass, thus requiring a lot more communication than a data parallel approach
- unless the advantages of model parallelism are absolutely critical (model doesn't fit on one machine), most research on large-scale training is done using data parallelism.
- Schemes involving a mix of data and model parallelism also exist: *hybrid parallelism*.

Hardware issues

- **I/O contention** with large data sets, or data sets with many small examples, and the data has to be physically stored on shared storage facilities.
- **Communication** bottlenecks during gradient-aggregation, due to high ratio between the number of parameters and amount of computation
- **Memory** bottlenecks for large networks, particularly when using memory-limited GPUs
- On large system such as **HPCs**, data are typically stored on shared file systems
  - Might be faster to copy data locally to worker node

Architectural choices

- **Your model doesn’t fit in the GPU memory?**
  - tune the model e.g. by reducing its connectivity (if that is acceptable) to fit the hardware
  - use model parallelism to distribute the model over multiple GPUs
  - use a data parallel approach on CPUs (if it does fit in CPU memory)
- **Your dataset doesn’t fit in the GPU memory?**
  - Make sure your data arrives fast enough to the GPU, otherwise revert to CPU
- Do you have access to a **system with a few GPU nodes, but thousands of CPUs**?
  - Development stage: run a limited number of examples (potentially even with a smaller model) on a single GPU, which allows quick development cycles
  - Production: may require CPUs because of memory constraints

Requirements for ML framework

- Run any ML algorithm of our choice in parallel
- Large datasets to be processed
- Multi-tenancy, so different users can request simultaneously ML pipelines
- An efficient resource management system for the cluster
- Support heterogeneous architectures
    - CPUs, GPUs, ...

ML as a Service (MLaaS)

CHALLENGES

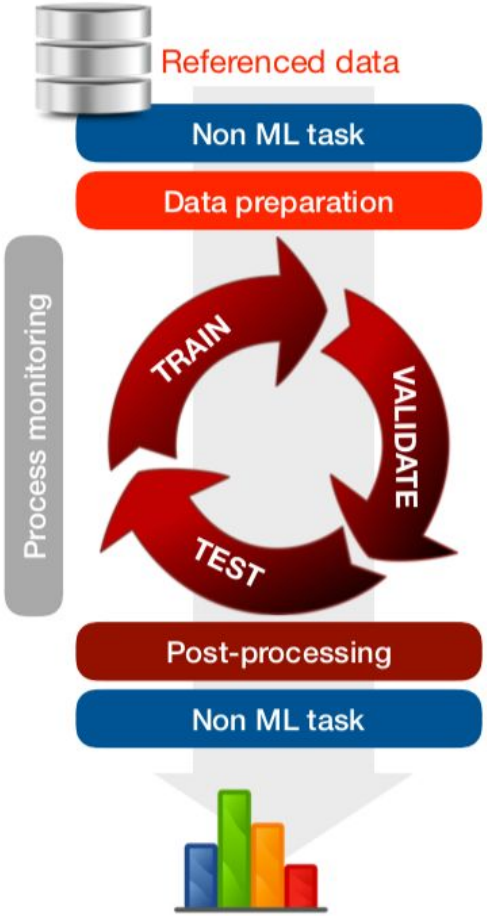
- Reconstruction
- Analysis
- Trigger
- Data quality
- Detector monitoring
- Computing operations
- Monte Carlo tuning
- ...

REQUIREMENTS

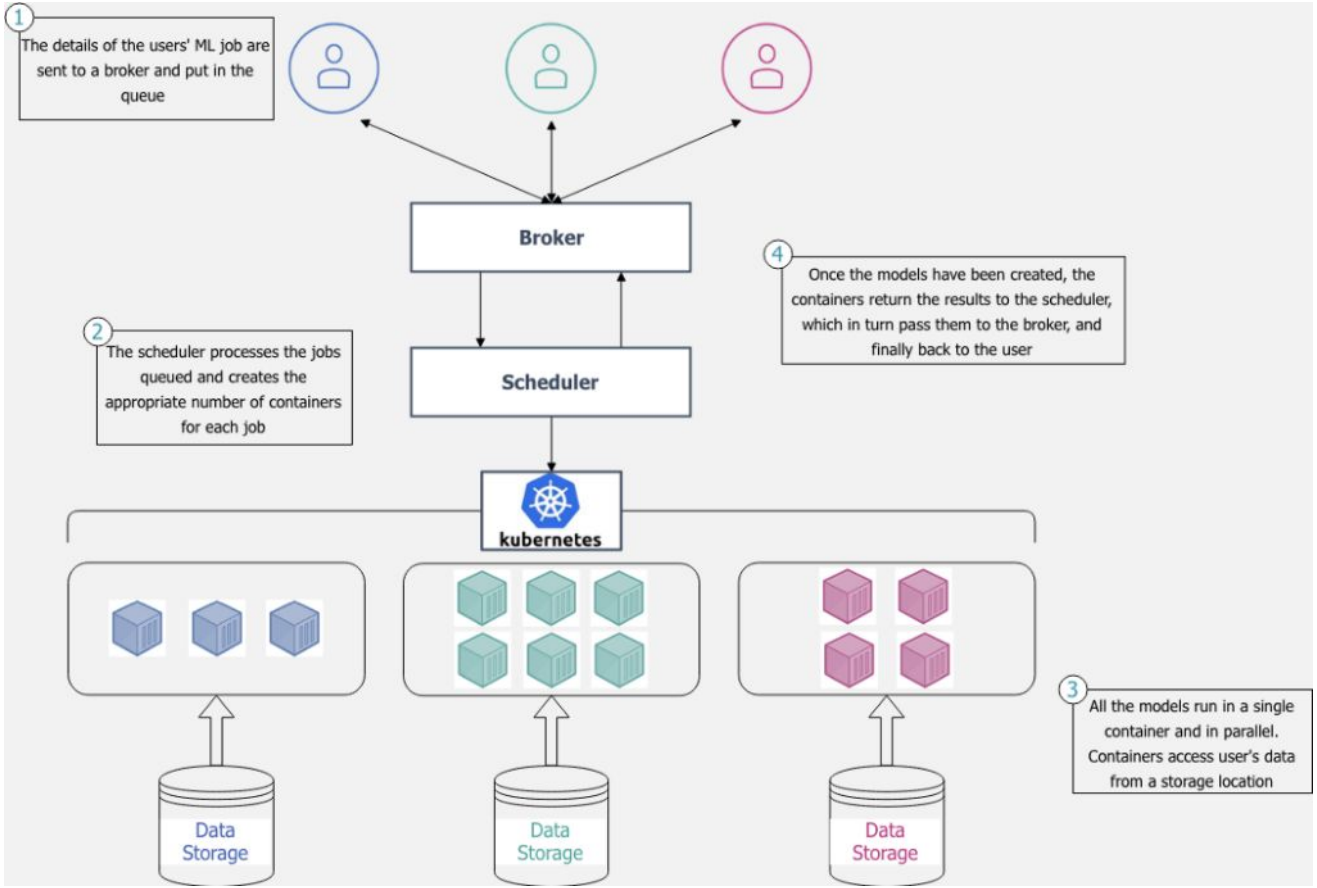
- Workflow definition
  - Results reproducibility
- Multi-tenancy (scheduling, authentication...)
- Parallel execution and scaling
- Data handling
- Ease of use and management
- ...

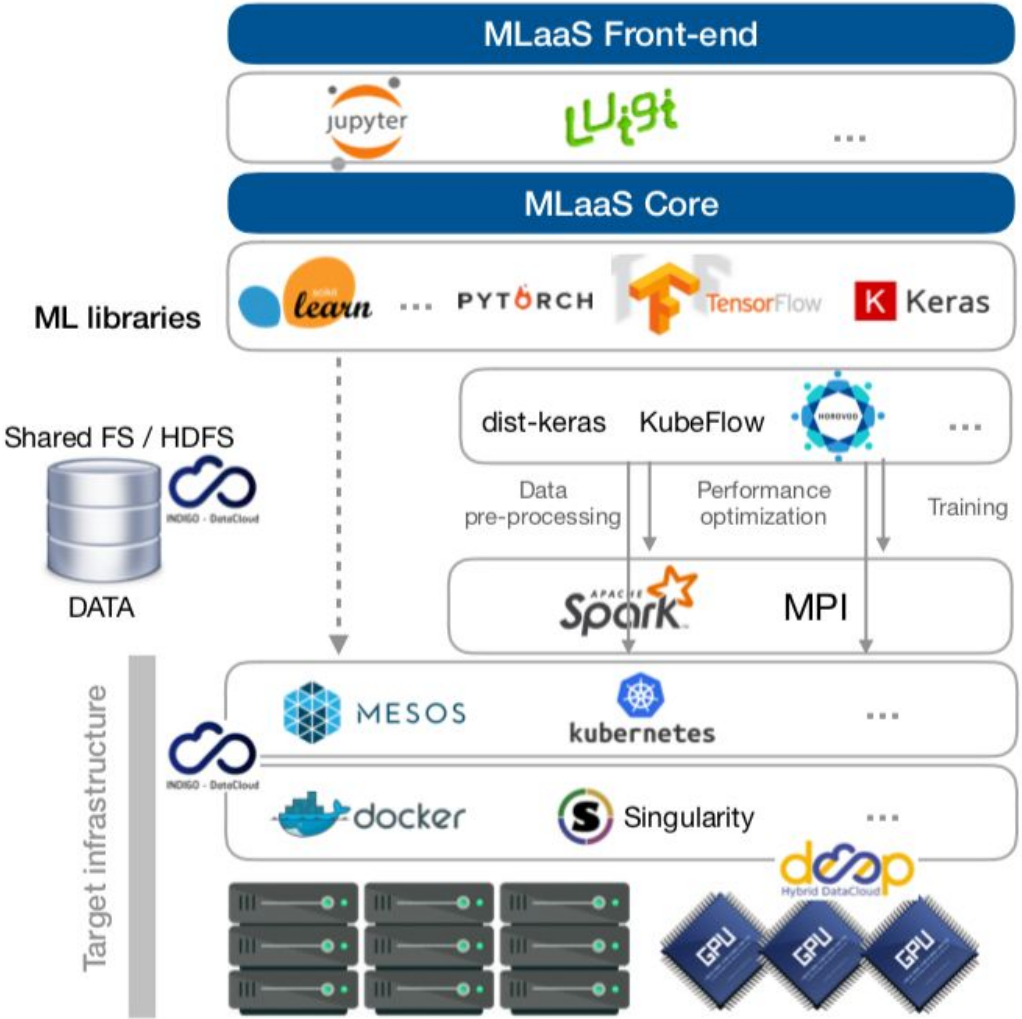
IMPLEMENTATION

- Lightweight virtualization
- Modularity
- Flexibility
- Heterogeneous back-end infrastructures
- ...



Example architecture





- Workflow definition
- Process Monitoring
- Authentication

Deep Learning framework

Distributed DL libraries

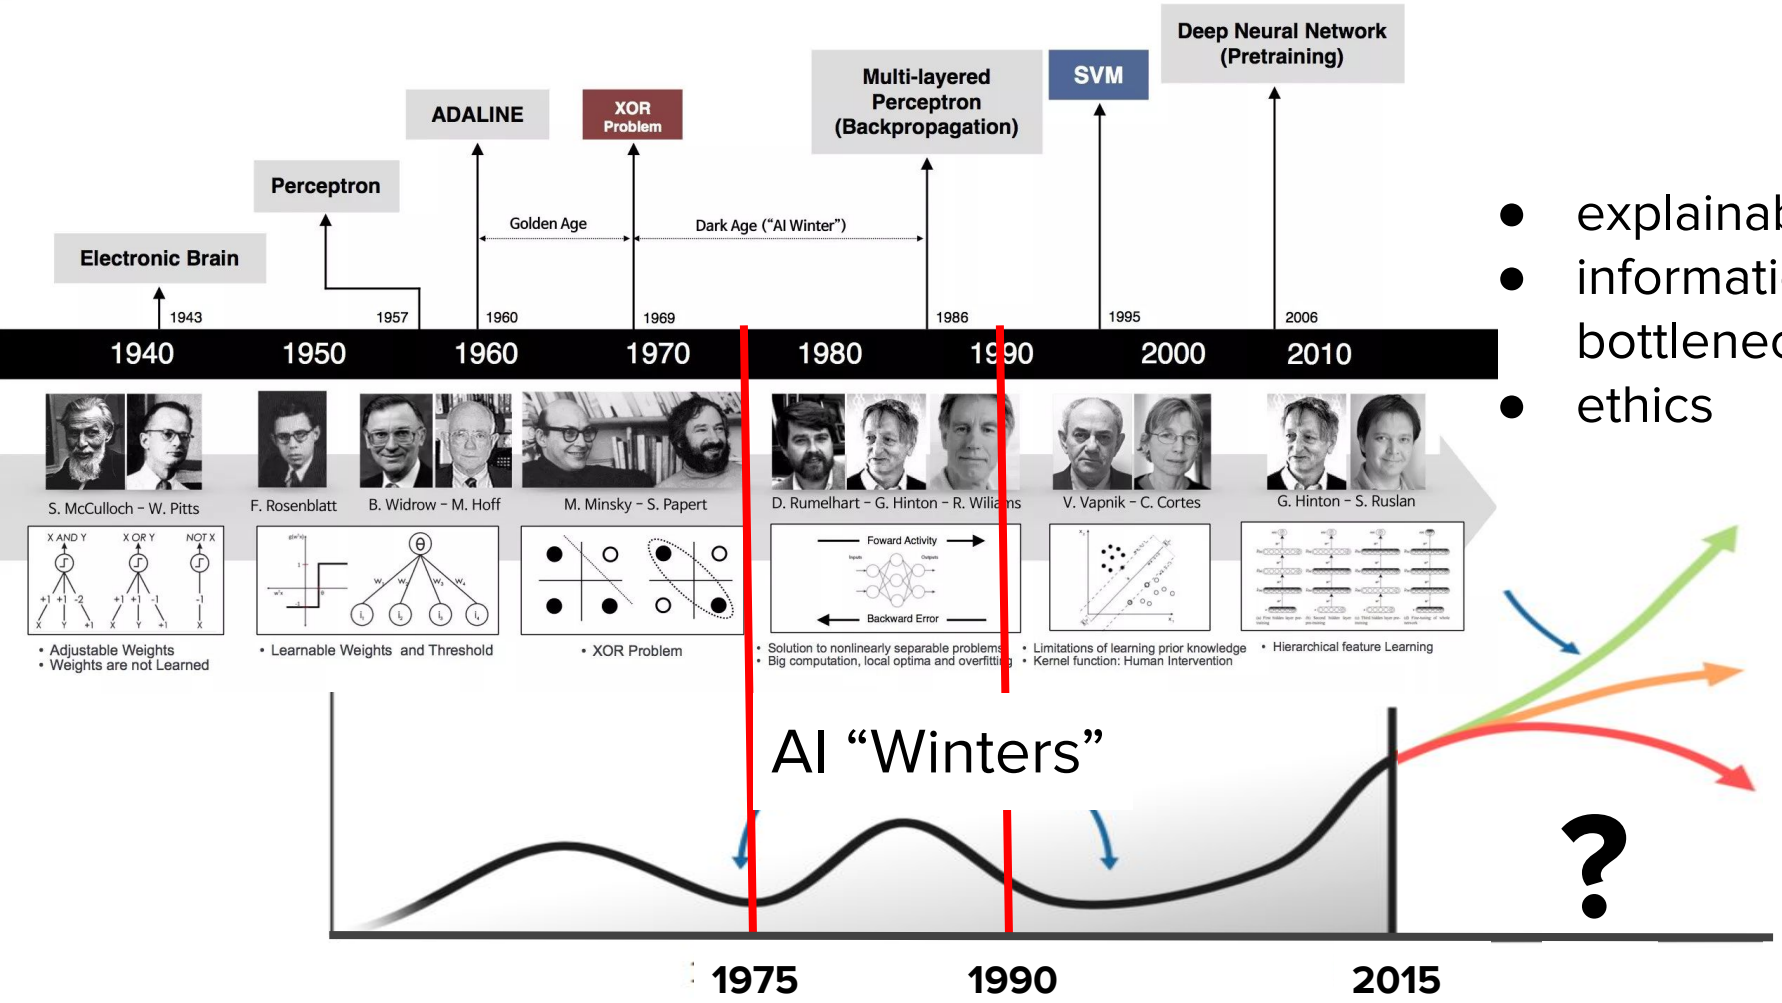
Cluster framework (parallelize task)

Orchestrator (schedule on resources)

Packetization and virtualization

Resources:

- Bare metal
- Infrastructure as a Service



- explainable AI
- information bottleneck
- ethics

Artificial General Intelligence

- **Common sense**:
  - Current systems may be easily fooled by just slight changes in the input data (for example image taken from another viewpoint)
  - Embed coordinate systems, whole-part relationship (capsules)
- **Abstract concepts**:
  - Current models may be able to distinguish between a jet and a tau, but do not know what a particle is
- **Creativity**:
  - Current models highly specialised and engineered to solve specific problems

[Murray Shanahan, Geoff Hinton]

Self Supervised Learning

- Supervised learning needs many labeled data
- Reinforced learning:
  - Not practical to train in real world (when no simulation is available)
  - takes longer than an average human for a machine to learn a new task
- **Self supervised learning:** Predict everything from everything else - learn representations, rather than learning specific tasks
  - Very large networks trained with large amount of data
  - Fill_ing the bl_anks - Word2Vec, Transformer architecture for NLP
  - Not (yet) so successful for continuous problems (image, video)

[Yann LeCun]

Consciousness Prior

- Current deep learning:
  - **System 1:** fast, unconscious task solving
- Future deep learning:
  - **System 2:** slow, conscious task solving like reasoning, planning
- How?
  - Learn by predicting in abstract space
  - Learn representations (low dimensional vector), derived using attention from a high dimensional vector
  - The prior: the factor graph (joint distribution between a set of variables) is sparse

$$P(S) = \frac{\prod_j f_j(S_j)}{Z}$$

Yoshua Bengio, arXiv:1709.08568 [cs.LG]

Outlook

- The field of AI/ML/DL is steadily progressing
  - Mainly driven by industry applications
  - Science should not stay behind
- Physics applications in a wide range of domains, and growing
- Great opportunities for cooperation with both industry and diverse scientific sectors, and to engage students
  - Foster the use of common tools/technologies
